*Regular Meeting, held Feb. 26, 1902.*

The President, Dr. T. H. Fenton, in the Chair.

#### Symposium on Cholecystitis.

Dr. J. McFARLAND, in a paper on "Pathology of Cholecystitis," stated that the gall-bladder may be congenitally absent without special disadvantage. The routes of infection of the bladder are through the blood vessels or lymphatics or from the intestine. The most common is the latter, through the duct. The bile becomes viscid andropy, the duct perhaps becoming partially or wholly occluded. The gall-bladder is distended and swollen, ulceration, abscess formation and perforation sometimes resulting. Recovery or chronicity may occur, if the latter the bladder will be found fibrous and contracted. One great cause of cholecystitis is cholelithiasis. The cause of the latter is not definitely known. Epithelial cells or bacteria perhaps serve as nuclei for the deposit of the bile salts.

Dr. JOSEPH SAILER read a paper on "Etiology and Diagnosis of Cholecystitis." The healthy gall-bladder is uninfected. The bile is not bactericidal, but does not supply much food for bacteria. The most favorable disease for the development of cholecystitis is typhoid fever. Quotations from several investigators were given to substantiate the latter view. In six cases with a history of typhoid fever, the author had found the typhoid germ present in the gall-bladder, and in one case cultures were grown from bile three months after it had been obtained from an autopsy. The typhoid bacillus had been found in gall-stones. Diagnosis is sometimes difficult and may escape attention. In appendicitis, laparotomy has taken the place of autopsy. Cholecystitis is, however, comparatively rare. If catarrhal jaundice be present the symptoms may be plain. The speaker cited the local symptoms, the conditions to be sought for by physical examination and recounted the general symptoms. Of the later are chill, fever of a hectic type simulating malaria, prostration and delirium. There may be an antecedent history of typhoid fever. The speaker referred to a case seen by him and Dr. Musser. The patient, a woman of 50, jaundiced, stools clay colored, anemic, had an elastic palpable mass below the ribs on the right side. Patient experienced a sensation of a sudden giving way in the abdomen. At the autopsy, three days later, the peritoneal cavity was stained with bile, and the gall-bladder was found with a small tear in the fundus. The common duct had a ball valve obstruction.

Dr. J. CHALMERS DA COSTA discussed the subject of "Surgical Diagnosis and Treatment of Cholecystitis." He said that the causes may be one or many genus, the character of the lesion depending upon the virulence of the infection and the resistance of the tissues. Chronic cholecystitis is usually without jaundice and the attacks may not be distinguished from gall-stones. The speaker recently operated upon a case supposed to be one of the latter. Curettage of the mucous membrane and maintenance of drainage for a time effected a cure. In another case gall-stones were found in the feces, but operation showed that the bladder had emptied itself of stones. Jaundice is rare in cases free from stones. The passage of plugs of mucus may simulate that of stones, but is less severe, and there is absence of tenderness over the gall-bladder. Some cases where doubt exists demand incision and drainage for a week or more. Croupous cholecystitis is rare, and the symptoms are identical with those of gall-stones. Simple empyema, acute, phlegmonous, suppurative and cholangitis with perforation are various forms of the affection.

The latter strongly simulates acute appendicitis, and in each, surgical interference is life-saving. An enlarged gall-bladder may be mistaken for a movable kidney. The directions given by Henry Morris were cited: "The gall-bladder is commonly a

movable abdominal tumor; attacks of jaundice probably occur; the bladder is palpated at the edge of the liver, the presence of stones at times giving the sensation of hardness; the bladder is movable only in a circle and not downward toward the pelvis. The kidney tends to stay in the loin when put there." The greatest care will sometimes fail to distinguish cholecystitis from appendicitis.

DR. S. SOLIS-COHEN, in a paper on "Medical Treatment of Cholecystitis," said that there is no one medical treatment. There is often difficulty in diagnosis. I have never seen a case of isolated cholecystitis. There are always other associated inflammations of the stomach or intestines. For the gastroduodenal catarrh, lavage is useful. Calomel, sodium phosphate or sulphate is often useful. Rest, regulation of the diet, mild laxatives and mercurials are common and are good measures. Sodium succinate, first recommended to me by Dr. Ellwood Wilson, 5 grains four or five times daily, I have often found excellent. Bile preparations are sometimes used with apparently good results. Foreign physicians rely much upon the spa treatment. The artificial salts of alkaline waters are easily prepared. Hydrotherapeutic measures and massage stimulate increased bile secretion and bodily functions and prevent complications.

DR. J. C. WILSON said in discussion: There are two states of inflammation, one a result of stones, the other independent of stones. The conditions may overlap. The conditions can, at times, scarcely be clinically differentiated. In my own experience I have recognized three common conditions, catarrhal cholecystitis, and thickening with or without adhesions accompanied with contractions. The first form I have recognized as a complication of enteric fever in a considerable proportion of the relapses of the latter. It is very frequent in enteric fever, recovery usually being prompt. Whether the disease is or is not accompanied by jaundice or stones, in cases of repeated colic, early surgical operation should be done.

DR. JOHN H. MUSSER believes that all forms of cholecystitis are infective, very frequently associated with stones. Contrary to the common experience, he has found, in the Philadelphia Hospital, more men than women affected with gall-stones. The speaker had seen three cases of cholecystitis associated with typhoid fever, and had perhaps overlooked many not suggested by local signs. Pneumococcus infection of the gall-bladder occurs conjointly with infection of the lungs. There is greater difficulty in distinguishing cholecystitis from pancreatitis than from any other disease. The etiology and the physical signs posteriorly are strong factors in diagnosis. A case of pancreatitis operated upon recently had effusion into the lesser peritoneal cavity.

DR. ERNEST LAPLACE holds that each case is one to itself according to what special germ causes the infection. Future work should be in the direction of finding the specific cause in each case. It is only about the gall-bladder and vermiform appendix that the methods of preantiseptic surgery exist. The day is not far distant when a frank attack of gall-stone colic will lead to operation.

DR. G. G. DAVIS said that in cholecystitis we should expect to find an enlargement of a sausage-like shape extending directly downward with tenderness at McBurney's point, but dulness reaching to the liver's edge. The surgical treatment now is where that of appendicitis was a few years ago. The profession is yet to be taught the seriousness of these affections. Usually there is greater danger in adopting a conservative course. In jaundice, hemorrhage being a great danger only a mild operation providing for drainage should be done.

DR. JUDSON DALAND called attention to the fact that stones often exist without symptoms; also to the danger of hemorrhage and to the failure of wounds to heal where jaundice is present.

DR. JOHN B. DEEVER believes that the surgeon should early claim these cases, and believes in the propriety of early operation, as much so as early operation in appendicitis. In operating he rarely leaves a gall-bladder. He thinks that no one can differentiate cholecystitis from appendicitis in every case.

DR. WM. E. HUGHES holds that if there is a history of gall-stones the case should be referred to a surgeon. If, however, the case be one of simple cystitis it is not a surgical disease. He has treated several of the latter cases and all have recovered. The fact was pointed out that pleurisy or congestion of the right lower lobe of the liver may be mistaken for cholecystitis.

## NEW YORK ACADEMY OF MEDICINE.

*Regular Meeting, Held Feb. 20, 1902.*

Vice-President, Dr. Charles L. Dana, in the Chair.

### Symposium on Vaccination.

Although this evening's discussion was styled a symposium on vaccination, it was rather a discussion on vaccine. It was opened with an introductory paper by Dr. Alonzo Blauvelt, Chief Inspector of the Division of Contagious Diseases of the Health Department, who described "The Action Taken by the Health Department on Report of a Case of Smallpox." He said that immediately upon receipt of the notification, a diagnostician of the department and a policeman proceeded to the address given and if the case was thought to be one of smallpox the patient was conveyed to the Riverside Hospital in a coupé or ambulance used specially for this work. Instructions were left at the house for the disinfectant and the health department vaccinator offered vaccination to all in the house. The children in the house were not allowed to attend school for three weeks, but the adults attended to their occupations as usual.

DR. M. J. ROSENAU, Director of the Hygienic Laboratory of the Marine-Hospital Service, read a paper upon "Dry Points Versus Glycerinated Virus from a Bacteriological Standpoint." He said that diluted glycerin was a favorable culture medium for bacteria, and in greater concentration it was not a true bactericide, killing bacteria only by a very slow process of dehydration. Moreover, glycerin gradually destroys the potency of vaccine. Dr. Rosenau then described a series of bacteriological experiments undertaken with a view to instituting scientific comparisons between glycerinated vaccine virus and dry vaccine points as regards the number of bacteria present. The material for the investigation consisted of 92 samples of vaccine obtained in the open market, representing the products of eight manufacturers. The 41 dry points gave an average of 4807 colonies per point and the 51 samples of glycerinated virus gave an average of 2865 colonies per tube. The figures presented were remarkable in that they showed an enormous number of bacteria in the glycerinated virus as compared with the dry points. The author endeavored to explain this result partly by the great variations in the quantity of vaccine contained in the samples of glycerinated lymph and also by the supposition that many of the makers of glycerinated virus placed their products on the market while yet too "green." He added that much of the contamination observed was unnecessary and was probably the result of the over-confidence in glycerin as a preservative. This investigation seemed to Dr. Rosenau as pointing clearly to the desirability of government control of vaccine production.

DR. F. S. FIELDER presented a carefully prepared report of tests that he had made to compare the value of the dry point with that of glycerinated vaccine virus. The glycerinated virus manufactured by the New York City health department was used in the tests and this was compared with ivory points made by eight different private manufacturers and with dry points prepared by the health department. The last mentioned were divided into lots: those points charged with serum exuding after having everted away the pulp used in the manufacture of glycerinated virus and those charged with the serum obtained after simply removing the top of the vesicle. It was stated that no great difference was observed in the action of these two lots of dry points. Of the health department dry points 25 per cent. were successful, while 60 per cent. of the insertions made with the dry points of private manufacturers proved successful. On the other hand, nearly 93 per cent. of the insertions made with the glycerinated virus were

successful. Severer constitutional symptoms were observed with the glycerinated virus, but this the author attributed to the use of "green" virus in all the experiments. Very few eruptions were noticed and these were mild, ephemeral and chiefly of an urticarial type. It was also noted that 78 per cent. of the cases successfully vaccinated with the health department dry points healed promptly and 8.8 per cent. healed slowly, while of those done with the glycerinated virus, 66 per cent. healed promptly and 17.2 per cent. slowly. The speaker said that he was not prepared to state how long the dry points would retain their potency, but he had ascertained that the glycerinated virus of the health department would yield 100 per cent. of successes after having been kept for nearly eight months.

DR. JOHN H. HUDDLESTON read a paper upon "Tetanus and Vaccine Virus." By bacteriological experiments on the feces of twenty-five calves fed on hay he had demonstrated the presence of tetanus germs in only two instances. His experiments also showed that glycerin exerted a distinctly inhibitory influence on the tetanus germs and that cultural tests were more delicate than animal inoculations in detecting the presence of tetanus. His conclusions were as follows: 1. The feces of calves fed on hay may contain tetanus germs; 2. these germs do not develop with glycerinated virus; 3. any form of vaccine virus—dry points or tubes of glycerinated virus—may be infected with tetanus and may convey it, but no form of vaccine increases the amount; 4. cultural tests for the presence of tetanus germs are somewhat more delicate than animal tests; 5. inoculation by scarification is not a favorable method of introducing tetanus; 6. it is probable that the greatest precaution against the production of infected vaccine virus lies in the maximum of cleanliness observed in a vaccine laboratory.

DR. FRANK P. FOSTER said that it was evident from the remarkable figures presented by Dr. Rosenau that there is a good deal of glycerinated vaccine on the market which does not possess the properties which should belong to good virus of this form. It was also evident that the dry points used by Dr. Fielder were very poor. Dr. Foster said that his experience in the past in the manufacture of vaccine had taught him that better virus was obtained from calves of six or eight months than from younger calves. Good dry points should certainly retain their potency for seven or eight months—indeed, if not merely dried but desiccated, it might be preserved much longer. If the term "pulp" was used to designate the whitish pulpy layer found beneath the epidermal portion of the pox, he would say that he had always been of the opinion that this was abnormal and should not be used for the manufacture of vaccine, inasmuch as it was made up of the necrosed tips of the papillæ of the derma.

DR. J. J. KINYON, of the U. S. Marine-Hospital Service, said that from experiments that he had made in the laboratory on methods of collecting lymph, he had found that the first part was quite rich in vaccinal material and the last portion comparatively weak. This might explain some of the differences in potency observed in dry points of different manufacture. It had been found very difficult to preserve the glycerinated virus for any length of time in the Philippines, so that it became necessary to use the lymph while still green. As a result, there were very many sore arms.

DR. HUDDLESTON said that the great variations observed in the number of bacteria found by Dr. Rosenau in glycerinated virus was to be explained in part by the fact that it was practically impossible to make a thoroughly homogeneous vaccine emulsion, so that some samples would contain more vaccine particles, and perhaps more bacteria, than others. There must be some solid matter in all good vaccine, for, it had been shown that if the virus were passed through a filter which would remove all solid particles, the filtrate was wholly inert. The white pasty matter referred to by Dr. Foster was curretting out and used in the manufacture of glycerinated virus. Both dry points and glycerinated lymph had been known to retain their potency for two years or more, but while this was interesting from a scientific point of view, it did not indicate at all the practical life of the vaccine. He was of the opinion that there was a decided difference in the quality of the vac-

cine obtained from the cow and from the calf, because the curretting could hardly be done so thoroughly in the older animal.

DR. ROSENAU said that it should not be forgotten that all dry vaccine points are not manufactured in the same way. Some manufacturers charge the points with the serum exuding from the old cross-hatch scarifications, while others mix the lymph with glycerin, set it aside for some weeks and then mix it with normal blood serum and allow it to dry on the bone points. As vaccinia was an epithelial infection, the glycerinated pulp, containing as it does the epithelial layer, should contain the maximum of vaccinal bodies.

## CHICAGO NEUROLOGICAL SOCIETY.

*Regular Meeting, held March 6, 1902.*

President, Dr. Daniel R. Brower, in the Chair.

### Hysteria.

DR. ELBERT WING reported the case of Miss H., aged 15, who complained of a constant ache in all of the teeth of the upper jaw, accompanied by tenderness, both the aching and tenderness being greatest on the right side. The pain is described as a dull, heavy ache, rather than sharp or lancinating, varies somewhat in severity and is present all of her waking hours. The tenderness is not great and not uniform in all of the teeth. The pain is influenced somewhat by cold, but not at all by heat. It is not increased by the acts of talking or eating. In May, 1901, the patient had an attack similar to this, in which the teeth of the lower jaw were involved. It began in a few of the teeth on the left side. Her dentist, drilled into these, destroyed the pulps and filled the root canals. This did not stop the pain and finally the affected teeth were extracted. This treatment, with variations, ran the circuit of the lower jaw, until all of its teeth were extracted and a plate of artificial teeth put in. About six weeks after the teeth were all extracted, the pain, diminishing gradually, ceased. Six weeks later, the pain began in the teeth of the right side of the upper jaw and had continued until this examination was made, Dec. 21, 1901. The dentist did not excavate or extract the upper teeth.

Three years ago the patient had what she described as "soreness in her scalp," which was not relieved until her hair was cut short. Then she had some trouble with her eyes, not inflammatory, in which she says she almost lost her sight. Later she had attacks of spasms. She says that one doctor stuck pins in her and said that there was nothing the matter with her. She has had no other illness and menstruation is fully established, regular and normal in every way. Patient's father has had "nervous trouble," is now well, and the family history is otherwise negative.

Examination shows a young woman, 5 feet 8 inches tall, large in proportion, in excellent general nutrition and full mammary development. Appetite good; no symptoms of indigestion; bowels act normally and sleep is good, except when disturbed by the pain in the teeth. Loss of sleep from this cause, she says, is considerable. Patient's appearance is that of excellent health. When alone with the examiner, the patient's manner was quiet and free from peculiarity, except lounging in her chair, but when her dentist, who seemed familiarly acquainted, was present, her manner was petulant and capricious. The thoracic and abdominal organs were normal.

Voluntary motor power was normal and symmetric. Tests for touch and pain were made with a camel's hair brush and common pins. Sensation to touch was slightly less throughout the left side. On this side there were areas of moderate size of diminished sensation over the upper half of the chest, the hypochondriac region, the outer and middle third of the thigh and two places on the leg. There was absence of pain to the prick of a pin over and just above the left breast and there was diminished pain sense in the areas partially anesthetic to touch and slight anesthesia over left scapula. Epigastric reflex was slightly less on left side; abdominal walls were symmetric; elbow-jerks were absent; knee-jerks present and fairly symmetric. The pupils react normally and vesical and

rectal control reported normal. There was moderate tenderness in the upper teeth, more pronounced on the right side, and some in the upper branch of the fifth nerve of the right side. There was no other tenderness. Physical examination was not carried further. The patient was referred to her home physician with the diagnosis of hysteria and the usual suggestions outlined for treatment.

DR. SYDNEY KUH recalled the case of a girl who presented herself at Czerny's clinic in Heidelberg, with the statement that she had swallowed a pin. She had considerable pain; her stomach was opened and a pin was found in the wall of the stomach. Patient returned subsequently two or three times, wanting to undergo another operation. The suspicion of the surgeon was aroused; he refused to operate a second time, as he was firmly convinced there were no more pins in the stomach. Dr. Kuh also detailed a case of hysteric deception which occurred in the practice of a country doctor. A girl claimed that she had swallowed a snake; that she could feel it moving about in the abdomen and insisted that something be done for its removal. Little attention was paid to her until one day they found her in front of the house apparently very ill. She had vomited and in the vomit there was a snake-like body, which turned out to be the gut of some animal.

DR. DANIEL R. BROWER mentioned a case which occurred in the practice of Dr. Fitch many years ago. It was stated that the woman's urinary secretion had been entirely suppressed, and that she was secreting urine by the gastric mucous membrane. He was called in consultation in this case. Dr. Fitch had the contents of the woman's stomach examined a number of times and always found urine present. Dr. Brower suggested that she be put to bed and some responsible person directed to watch her. This was done and it was found that the woman would urinate and then swallow the urine.

DR. LONOR mentioned a patient who had some of her teeth extracted on account of a supposedly distressing condition of them. She exhibited the usual stigmata of hysteria. She was referred to him with the recommendation that the dental nerve be trephined for excessive pain; but on examination he found nothing wrong with the patient's mouth and said the case was purely hysterical.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Local Treatment of Leucorrhea.

The following is recommended by Lutand, to be used locally in treatment of leucorrhea:

|                         |       |     |
|-------------------------|-------|-----|
| R. Pot. chloratis ..... | 3ss   | 45  |
| Tinct. opii .....       | 3i    | 31  |
| Aq. picis liq. ....     | O. ii | 596 |

M. Sig.: One-half a glass to be used in a quart of water as a douche night and morning.

### Thrombosis of Femoral Vein in Typhoid Fever.

J. M. Anders, in *Med. News*, recommends the following ointment to be applied along the course of vessels:

|                                     |          |
|-------------------------------------|----------|
| R. Unguenti ichthyol (10 per cent.) |          |
| Adipis lane hydrosi, aa.....        | 3ii 7 50 |
| Ung. belladonnae .....              | 3ss 15   |

M. Sig.: Apply locally three or four times a day over the course of the vein.

### The Treatment of Fever.

Ernest Jendrassik, in *Ther. Month.*, states that cold bathing in fevers, by abstracting a certain number of calories which immediately have to be replaced, causes overwork of the system, exaggerated combustion, which means a considerable loss of substance and rapid return of the fever: in many ways it resembles the old-fashioned bleeding. According to his statement it is sedative, refreshing, tonic and hygienic, but not antipyretic.

He regards phenacetin as the best in high fevers, especially in children, but occasionally it will have to be replaced by antipyrin. One to one and a half drams should be given at one dose. The action will last about six hours, and when the temperature begins to rise again the dose should be repeated and thus four doses may have to be given in the twenty-four hours. He believes that insufficient dosage is responsible for the lack of results of the employment of these agents.

[If the author is correctly quoted he certainly is advising practitioners to tread upon dangerous ground in giving a dram and a half of phenacetin at one dose.]

### Treatment of Influenza.

The following formulae are noted in *New York Med. Jour.*, in the treatment of the different organs involved in influenza:

To disinfect the ears:

|                                  |       |      |
|----------------------------------|-------|------|
| R. Hydrarg. chloridi corros..... | gr. i | 06   |
| Alcoholis .....                  | 3iss  | 5 60 |
| Aq. destil. ....                 | 3ii   | 62   |
| Glycerin .....                   | 3iv   | 124  |

M. Sig.: Instill a few drops into the ear three times a day.

For the nose:

|                      |         |    |
|----------------------|---------|----|
| R. Menthol .....     | gr. iii | 20 |
| Olei petrolati ..... | 3ss     | 16 |

M. Sig.: Instill a few drops into the nose three times daily.

For the throat:

|                    |           |     |
|--------------------|-----------|-----|
| R. Alcoholis ..... | 3ss       | 16  |
| Resorein .....     | gr. x     | 66  |
| Salol .....        | gr. viiss | 50  |
| Aq. q. s. ad.....  | O. ss     | 248 |

M. Sig.: To be used frequently as a gargle; or:

|   |       |     |
|---|-------|-----|
| R. Acidi salicylici .....               | gr. v | 30  |
| Spts. menthae pip. q. s. ad solutionem. |       |     |
| Aquæ q. s. ad.....                      | O. ss | 248 |

M. Sig.: As a gargle.

To disinfect the room:

|                           |            |
|---------------------------|------------|
| R. Acidi carbol.          |            |
| Acidi salicylici, aa..... | gr. lxxv 5 |
| Menthol .....             | gr. xxx 2  |
| Alcohol .....             | 3viii 248  |
| Tinct. eucalypti .....    | 3i 3 75    |

M. Two to four tablespoonfuls in 16 ounces of water, to be evaporated in the room.

### Enlarged Spleen in Chronic Malaria.

Lyon, in *Le Prog. Medical*, recommends the following local and general treatment of enlarged spleen in malaria:

|                        |         |      |
|------------------------|---------|------|
| R. Iodoformi .....     | gr. xlv | 3    |
| Ext. belladonnae ..... | 3i      | 3 75 |
| Ol. menth. pip. ....   | gtt. xx | 1 33 |
| Adipis lane .....      | 3ii     | 60   |

M. Ft. Ung. Sig.: Apply locally twice a day with friction.

For the general condition the following:

|                             |           |      |
|-----------------------------|-----------|------|
| R. Acidi arsenosi .....     | gr. 1/100 | 0006 |
| Iodoformi .....             | gr. i     | 06   |
| Ferri et potass. tart. .... | gr. i     | 06   |
| Ext. belladonnae .....      | gr. ss    | 03   |
| Quininae sulph. ....        | gr. 1/3   | 02   |
| Ext. nucis vom. ....        | gr. 1/6   | 01   |
| Ext. valerianae .....       | gr. i     | 06   |

M. Ft. pil. No. i. Sig.: Take two such pills at noon and two at night before meals.

### Diarrhea in Tuberculosis.

According to the *Pac. Med. Jour.*, the following is of great service in checking the diarrhea in tuberculosis:

|                           |         |     |
|---------------------------|---------|-----|
| R. Ichthoformi .....      | gr. v   | 33  |
| Tannalbin .....           |         |     |
| Bismuthi subgal., āā..... | gr. x   | 66  |
| Codeinæ sulph. ....       | gr. 1/4 | 015 |
| Olei menth. pip. ....     | m. 1/4  | 015 |

M. Ft. chartula No. i. Sig.: One such powder every two to six hours.

### Chalazion (Retention Cyst).

In the treatment of a cyst of the lid where the Meibomian gland is occluded, which may also be caused by errors of refrac-

tion, he recommends that the tumor be evacuated from the conjunctival surface of the lid, first anesthetizing the parts with the following:

|                              |           |    |    |
|------------------------------|-----------|----|----|
| R. Coetinae hydrochlor. .... | gr. xviii | 1  | 20 |
| Acili borici .....           | gr. x     |    | 66 |
| Aq. destil. q. s. ad.....    | 3i        | 31 |    |

M. Sig.: Use as a local anesthetic.

#### To Diminish Severity of Convulsion in Epilepsy.

The following is recommended by Yeo to lessen the frequency and severity of the convulsions in epilepsy:

|                              |         |    |  |
|------------------------------|---------|----|--|
| R. Morphina sulphatis .....  | gr. iss | 09 |  |
| Tinct. veratri viridis ..... | 3ss     | 15 |  |
| Aque q. s. ad.....           | 3ss     | 15 |  |

M. Sig.: Inject 20 minims hypodermically during or before a convulsion.

The following containing sodium borate is sometimes of service in treatment of epilepsy:

|                        |      |    |    |
|------------------------|------|----|----|
| R. Sodii boratis ..... | 3iii | 11 | 25 |
| Glycerini .....        | 3i   | 31 |    |
| Aque q. s. ad.....     | 3iii | 93 |    |

M. Ft. mistura (dissolve the sodium borate in warm glycerin). A teaspoonful to a dessert-spoonful three times a day.

#### Chronic Emphysematous Bronchitis in Children.

The following is frequently used, according to *Amer. Med.*, in treatment of the above form of bronchitis in children:

|                        |          |    |    |
|------------------------|----------|----|----|
| R. Arseni iodidi ..... | gr. ivss | 29 |    |
| Aq. destil. ....       | 3iss     | 46 | 50 |

M. Sig.: Begin with 5 drops in water, wine, or milk twice a day after meals, to be increased morning and evening until 10 to 20 drops have been added, according to the age and tolerance of the patient. The maximum dose should be retained for one month and then gradually decreased until 5 drops are taken.

#### Sodium Persulphate in Tetanus.

Gelibert, as stated in *Can. Pract. and Rev.*, gives account of numerous experiments with injections of sodium persulphate in tetanus. It was found that injections in animals of poisonous doses of tetanus toxin were antidoted if followed at once by a subcutaneous injection of sodium persulphate. The fresh and pure salt was used. These results were not obtained if some minutes elapsed between the injections. The use of the soda preparation, however, has an invariably favorable action on the tetanic contractions. The author gives the history of two cases of tetanus developing in children which were treated by the soda injections and recovery occurred in each instance, although the cases were serious. He injected 10 cubic centimeters of a 5 per cent. solution three or four times daily.

[The experiments as carried out by him on animals, showing that the antidote must be given within a few minutes after the introduction of the tetanus toxin, would certainly not prove its efficiency in counteracting tetanus in man, for the reason that the period of seven to fifteen days may elapse before tetanus, following an injury, develops.]

#### Otorrhea.

The following has been used with success in treatment of otorrhea:

|                            |     |   |    |
|----------------------------|-----|---|----|
| R. Ferri perchloridi ..... | 3ss | 1 | 90 |
| Alcoholis .....            |     |   |    |
| Aq. destil. āā.....        | 5i  | 3 | 90 |

M. Sig.: Three or four drops to be instilled into the external auditory canal two or three times a day.

### Medicolegal.

**Liability for Refusal of Admission to Hospital.**—The Court of Appeals of Kentucky says, in *Illinois Central Railroad Company vs. Gheen*, that it appeared that each employe on a certain division of the road, who was employed as much as four days in a month, contributed to the maintenance and support of a hospital. The sum payable was fixed according to the wages earned per month, the amount payable being

withheld by the paymaster and turned into the hospital fund held by the company's treasurer. The hospital association was not incorporated, but it had a board of directors who were such, save two, by reason of the official position with the road. The surgeon in charge was practically appointed by the company's chief surgeon. The men who contributed the monthly assessment to pay the hospital expenses had, in fact, no voice in the management or control of the hospital, save and except that of giving certificates of admission thereto to subordinate employes when sick or injured. These facts, the court holds, would have authorized the peremptory instruction of the jury in this case that if the employe who instituted this action had been engaged more than four days he was entitled to admission into the hospital, and if he was refused permission to enter, or certificate entitling him to transportation and entrance to the hospital, and was injured by such refusal, he was entitled to recover damages. But where he was employed in one county, and in that county refused by his foreman a certificate entitling him to admission into the hospital, the road running through that county and there being a chief officer and agent of the company, to-wit, a division superintendent, resident therein, the court holds that the cause of action accrued wholly in that county, giving the Circuit Court thereof jurisdiction of the cause, although the hospital was in another county. Then, it says that the general and universal rule of law in regard to damages is that every person must do all that can reasonably be done to render the damage for any act or omission as light as possible. Under this rule, this employe, when he was refused admission to the hospital, if such was the case, was bound to keep the consequent injury and damage as light as possible. To do so, he should have employed medical and surgical attention to cure his hand, or, at least, to arrest other or further injury. For such services and attention, or the cost thereof, the company, if liable at all, would be required to pay. But the proof was that he failed to use all means to prevent further injury to himself, contenting himself to accept the services and treatment of the company's local surgeon, who seemed to have pursued the same treatment given at the hospital. Yet, if that surgeon was unable, for any reason, to give him proper and necessary treatment to his wounds, it was his duty to procure elsewhere such attention. If he failed to do so, he could not charge the company with the consequent loss, suffering, or injury he received by his own failure to procure medical and surgical attention. But he could recover the reasonable cost of such medical and surgical attention that would have equaled that which he would have received at the hospital if he had been admitted. He was entitled, if at all, to the skilled surgical attention he would have received at the hospital, including board, transportation, and such accommodations and charges that the hospital would furnish its patients. If the company refused to furnish such, and was bound to do so, he could and should have sought such attention elsewhere, and for the reasonable cost thereof the company would be liable. The hospital was to furnish medical and surgical attention, and to nurse and care for the patient who was admitted therein. If the company was liable under the proof, its liability was for failure to furnish these things, and the damage for such failure was the reasonable cost at which such care and attention, board, and medical and surgical skill could have been obtained, as well as cost of transportation to the nearest suitable place where such attention could be had.

1. **X-Ray Treatment of Malignant Growths.**—The following are the conclusions of Morton's article: What is accomplished by the x-ray? 1. Relief from excruciating pain and constant suffering, often immediately. 2. Reduction in the size of the new growth. 3. Establishment of the process of repair. 4. Removal of the odor, if present. 5. Cessation of the discharge. 6. Softening and disappearance of lymphatic nodes. 7. Disappearance even of lymphatic enlargements not directly submitted to treatment and often at some distance. 8. Removal of the cachectic color and appearance of the skin. 9. Improvement in the general health. 10. Cure, up to date, of a certain number of malignant growths.

2. **Yellow Fever.**—Doty replies to Souchon's article, which appeared in the *Medical Record* of December 28, and claims that nothing has effectually proven yellow fever to be transmitted by personal contagion, clothing or bedding, or proven that the mosquito is not the medium of infection in yellow fever. He quotes from the records of 1798 and 1806 in support of his point of view and reviews the facts deduced by Souchon and others which are interpreted by them as showing the need of quarantine. He is satisfied that we have reasonably conclusive evidence that yellow fever is not communicated by fomites.

3. **Pneumonia.**—The increasing mortality of pneumonia is noticed by Burt, who suggests as prophylactic measures, aside from disinfection of pneumonia expectoration, avoidance of undue exposure to the weather, ill ventilated assemblages, reasonable attention to sanitation, temperance in eating and drinking, daily bathing to insure healthy action of the skin and regular exercise in the open air with special reference to complete respiration. There is nothing better, he says, to purify the blood and thus fortify the system against infection than systematic deep breathing out of doors while briskly walking or engaged in horseback riding. Frequent changes of underclothing are also desirable. Lobar pneumonia, he says, is universal in diffusion, infectious in nature, unsurpassed in frequency and fatality. The mortality can be reduced, if it can not be eradicated, only by incessant sanitary promulgations.

4. **Diabetic Coma.**—Mayer describes the symptoms of diabetic coma, its causes, diagnosis and pathology, holding that—of the various hypotheses that have been advanced—only two seem to be tenable, namely, that of acidosis or acid intoxication and that of specific toxemia, as taught by Klemperer and von Noorden. One is really a continuation of the other. He notices the theories which might suggest treatment, the experiments of Schwarz with glyconic acid, and remarks that an other rational method would be the introduction in the system of a sufficient quantity of ammonia to unite with the various acids found in the condition of acidosis, so that when neutralized the acid intoxication will be reduced, the alkalinity of the blood kept at its normal and the disintegration of proteids prevented. He believes he has accomplished the same results as Schwarz in averting coma by the administration of very large doses of urotropin, and reports a case. The patient was given as much as 20 to 60 grains daily for a considerable period, together with bicarbonate of soda. His reason for using urotropin is that it is a chemical combination of ammonia and formaldehyde, which in the presence of acid splits up into its component parts. This separation takes place in the kidneys, the ammonia being absorbed by the kidneys themselves, thus entering the circulation and neutralizing any acids, while the formaldehyde passes out with the urine. The patient died of asthenia, but coma was apparently averted.

5. **New Test for Albumin.**—The test here described by Fuhs consists in mixing equal volumes of urine and the emul-

sion of equal parts of carbolic acid and glycerin. This makes a perfectly transparent and highly refractive liquid, with normal urine, but if albumin is present, produces a white turbidity, which remains in spite of agitation and does not precipitate. The test is very sensitive, showing the presence of 0.1 per cent. of albumin in the urine, the degree of turbidity corresponding to the amount of albumin contained.

**10. Rectal Valves.**—Martin's article is a reply to one by Bodenhamer appearing in the *New York Medical Journal* for December 28, which was briefly noticed in THE JOURNAL of January 11, p. 130. He reports and illustrates cases which demonstrate, he thinks, the existence of rectal valves and their effects in producing constipation. Congenital valvular obstruction is, he thinks, not uncommon, though he has met with but comparatively few cases in adults. It may be more frequent in early life, children gradually growing out of it with the growth of the rectum, but one skilled in proctoscopy can tell the patient after examination whether or not he as a child suffered from difficult defecation.

**12. The Civilized Indian.**—The condition of the New York Indians on the reservation of Cattaraugus is described by Lake, who finds that they have seriously degenerated under civilization both physically and mentally.

**14. Vasectomy.**—Sharp recommends the performance of vasectomy in hereditary degenerates liable to propagate their defects. He has performed it on 42 patients and claims that it does not impair the sexual power, but improves the physical and mental condition. The method he has adopted lately is the English one which selects the scrotal region as the site. Grasping the vas between the thumb and index finger, make a longitudinal incision about three-eighths of an inch long and sever the vas. This ends the operation and the scrotal wound is not closed. He believes the authority should be given to render every male sterile who passes as an inmate, the portals of the almshouse, insane asylum, institute for feeble-minded, reformatory or prison.

**18. X-Ray Burns.**—Codman reviews the literature of accidental x-ray burns and discusses the pathology, classification, etc. The total number of cases which he has been able to find reported is less than 200 and he asks how many exposures this represents. He assumes that these statistics would be drawn from over 1,000,000 exposures and therefore only about 1 case in 5000 has been injured and less than one-half of these seriously. If we make doubly sure by assuming five times as many as reported, we find that only one case in 1000 has been injured. Again, if we include the past year taking only the cases in account that we find, there are 1 or 2 in 200,000. This evidently makes the case harder for the operator if a burn should occur. The largest number reported in any one year since 1897 is 23, and this probably includes a number of cases occurring in earlier years. Only one was reported in 1901. The actual cause of the burn is not known. Most writers agree that it is not heat, nor the brush discharge, nor the photographically active x-ray itself, but some form of energy radiating from the platinum terminal with the x-ray and probably closely related to it and to ultra-violet light. X-ray injuries are classed by the author in five divisions. The first he calls skiagrapher's dermatitis, occurring usually in workers with the x-ray and due to repeated short exposures. These cases are usually mild, but may go on to ulceration and gangrene. The skin generally remains chapped and rough, the wrinkles are obliterated by the swelling and the nails are affected. In the worst form the skin is entirely destroyed and the tendons and joints are involved. The next three classes occur accidentally in patients who are exposed once or several times at short intervals for skiagraphy and may be directly compared to burns of the first, second and third degree. The fifth group includes cases where some internal lesion is attributed to the x-ray, but the author does not find any reason to believe in its existence. Codman agrees with the balance of opinion which attributes these results to a primary action on the trophic nerves of the blood vessels and skin. The slowness of their appearance, the progressive character and failure to react to stimulating treatment bear out this view. The severe lesions are atrophic ulcers rather than burns. Of the cases

where the character of the lesion is recorded, 167 in number, 33 were skiagrapher's dermatitis, 14 were of the first degree, 29 of the second, and 71 were of the third. As regards the machine used, where the kind of apparatus was recorded, 11 were due to static machine, 3 severe; 11 were due to the Tesla coils, 5 severe; 40 were caused by forms of induction coil, of which 18 were severe. It is probable that coils may have been used much more than static machines or Tesla apparatus, and he notices the general impression among experts that the static machine is the least dangerous; but this shows that it certainly is not free from danger. In only 16 cases were the spark length and other data recorded. The spark length varied from 4 to 12 inches. In many cases the quality of the primary current is noted, but since the tube is actuated by a secondary current the figures have little value, *a priori*. However, the greater the amperage of the secondary current, the greater the chances of danger provided the voltage also is considerable. The quality of the tube is usually reported as soft and soft tubes are supposed to have more therapeutic influence. It is probable that the distance from the skin and the time of exposure have more influence than this factor. The maximum recorded distance from the tube to the skin in cases of injury was 50 cm. (statement of the patient), the minimum recorded distance from the tube to the skin 1 cm. The maximum recorded time of exposure of skin is 20 hours (in 10 exposures), the minimum recorded time 5 minutes; other data are not given. There is probably considerable inaccuracy in these figures, and Codman makes calculations showing the standard of comparison to represent the total exposure in a given case expressing the total time and distance. This is based on the simple law of radiation of light or other energy. From this he reduces all to a uniform figure, giving the formula, time divided by twice the distance equals the equivalent exposure in minutes at one inch distance. Taking the recorded cases he finds that the minimum exposure producing injury was equal to .05 of a minute at a distance of one inch. According to the formula given it would require 5 minutes exposure to produce the same injury at ten inches distance and nearly one-half hour at 24. The idiosyncrasy of the patient is, of course, to be considered a factor which can not be calculated or controlled. He adopts, making the calculations from all the facts, as a standard therapeutic exposure, 10 minutes at six inches, which is equal to .28 at one inch.

**19. Chicken-Pox.**—The views of Hebra, Kaposi and others as to the identity of chicken-pox with variola are mentioned by Schamberg, who then reports an epidemic of chicken-pox occurring in children who were just recovering from a variola outbreak. The only relationship he maintains that exists between chicken-pox and smallpox is the occasional strong resemblance, neither exerting any immunity against the other.

**21. Colon Bacillus.**—The conclusions of Rosenberger are given as follows: 1. That, while not affording a specific reaction in the case of the bacillus coli communis, neutral red agar should be classed as a valuable differentiating medium. 2. The typhoid bacillus, while it does not cause a fading of the color of the medium, never gives rise to the fluorescence noticed in some cultures of the bacillus coli communis. 3. Further, the test medium should not be depended upon as the only differentiating one in the examination of water, as several very common bacteria found in water give the same reaction.

**23. Venom and Antivenene.**—McFarland's article is continued, and in this issue consists mainly of a review of the literature.

**24. Apomorphin in Alcoholism.**—The author's attention was called to the use of apomorphin in alcoholism by an article by Dr. Douglas in the *New York Medical Journal*, and they give a review of reports of its similar use in the literature and the statements as regards the hypnotic action of the drug. They report the results of experiments made in the Bellevue Hospital with the use of this drug, having employed it in about 300 cases both of acute and chronic alcoholism and delirium tremens. They find that it is a decided hypnotic and sums up their conclusions thus: 1. To obtain a hypnotic action with apomorphin it should be given hypodermically. 2. The dose can not be fixed. It is best to begin with a small

dose—1/30 gr. or less—and to repeat this or give a slightly larger dose within a short time. Further doses should not be given after vomiting occurs, until several hours have passed. 3. Doses repeated in two or three hours have but little beneficial effect. 4. The administration of apomorphin should not be repeated in patients who are weak. 5. The duration of the hypnotic action is only a few hours and when the patient awakes his condition is practically unchanged, except in "ordinary drunks." 6. The best results are obtained from apomorphin when it is followed in two or three hours by some recognized hypnotic, as bromid, chloral or paraldehyde. 7. Solutions of apomorphin are unstable, and should be freshly made for use. Old solutions should never be used. 8. Apomorphin may be employed as a hypnotic in selected cases of alcoholism. We obtained the best results in "ordinary drunks" and in cases verging on delirium tremens. But in some of these cases the drug has no effect whatever. 9. The administration of apomorphin to patients in delirium tremens is, in our experience, without beneficial result, and may even be attended with danger from its depressing action."

**26. Proteosuria.**—Among the proteid products occurring in the urine under various conditions are proteoses, which seem to be chemically identical with those formed normally in the gastro-intestinal tract during the digestion of albuminous matter. Mosenthal and Gies have investigated the statement of Freund in regard to the method of detection of peptone in the urine and feces and point out that he has given a rather wide signification to the term peptone and seems to have had proteoses in mind. His method is a simple one, consisting in acidifying 10 c.c. of urine with acetic acid and then treating with 20 per cent. neutral or basic lead acetate. The milky mixture is then boiled thoroughly and the precipitate filtered off. The filtrate is then treated with potassium hydroxid as long as lead hydroxid continues to form. The mixture is then boiled again for a minute or two. The filtrate, it is claimed, is entirely free from urobilin and contains a little more than 90 per cent. of the proteose originally present in the urine. This may finally be detected with the biuret reaction. From numerous experiments to test the validity of this method, examining not only urine and feces, but normal urine treated with Witte's peptone, gelatins, various diuretics, albumin, ox blood, gastro-intestinal mucus, etc., positive results were obtained though they should not occur in the normal excretions. The results show, they think, that Freund's method is not a differential process and can not be safely applied to the urine or feces as a peptone test. They show that the peptones, proteoses and gelatins may each give positive results with it in the urine and feces and that sero mucus in the urine might also affect the final reaction.

**28. Sprue or Psilosis.**—Musgrave has studied this condition in soldiers coming from tropical countries and remarks on the failure to notice it in medical literature. It consists in an inflamed, eroded condition of the tongue and mucous membrane of the mouth, associated with flatulent dyspepsia, pale, copious and generally loose, frothy, fermenting stools, wasting anemia and irregular alterations of exacerbation and quiescence and a tendency to relapse. It follows prolonged residence by whites in the tropics. The disease in the alimentary canal and mouth regions consists of superficial erosions and ulcerations and may extend to the esophagus. In at least 13 of the 16 cases which came under Musgrave's care it existed as a complication or symptom of other diseases. The cases are reported in detail. In the majority, amebic dysentery was the underlying condition. (The article is to be concluded.)

**32. Wounds of the Hand.**—Whitacre reviews the various conditions following wounds of the hand and their treatment. First he speaks of simple felon occurring on the fingers or palm of the hand and insists on the importance of free incision under local anesthesia with the ethyl chlorid spray. He urges absolute cleanliness in the after-treatment and advises the use of antiseptic salts such as a one per cent. solution of aluminum acetate, the use of continuous hot baths, free drainage and wet dressings. A somewhat similar treatment follows acute diffuse cellulitis infection. He calls attention to

the importance of treating every kind of wound of the hand with the possibility of such infections in view. He describes the symptoms, but the details of the article are too elaborate to be fully mentioned here. In conclusion he mentions dog bites and insists on the importance of ascertaining the condition of the dog and if it proves rabid, following up with specific treatment as carried out in the Pasteur institutes of New York and Chicago. For preventive cauterization against infections he recommends 10 per cent. solution of chlorid of zinc, as its action goes deeper in the tissues than that of any other agent.

**35. Serotherapy in Epilepsy.**—This article by Ceni, which took the Craig Colony prize, covers the subject of serum injections in this condition. Starting with the autotoxic theory Ceni was led to consider the blood serum of epileptics as having therapeutic possibilities. He tried first to study the effects of small doses of epileptic serum injected into other epileptics, but no results worthy of mention were obtained. He then attempted to see if progressive doses of the same serum would render an epileptic more resistant to the dangers or action of poisons circulating within him. He made his first experiments upon animals and found that they suffered no permanent deleterious effects, but increased steadily in weight. He then tried it on patients using both their own serum and that of other patients, maintaining the most thorough asepsis and reports in this installment of his article 8 cases out of 10 thus treated. They have been under observation during a period varying from one to two years and all presented the severest form of idiopathic epilepsy, both as to number and intensity of motor crises and as to the presence of psychic or sensorial phenomena. He obtains his serum from the patient, carefully ascertaining his condition beforehand to avoid transmitting disease; divides the serum into small bottles holding 10 c.c. each, adding only some camphor. To insure preservation he has long used fractional sterilization, which at low temperature has no influence on the action of the serum. He always begins with 3 to 5 c.c. and increases gradually up to 10 or 20 c.c. in thirty or forty days. The patient reacts violently to the first injection, however small, and this progressive method is therefore necessary. During the first month he injects into the glutei at intervals of a few days, in increasing doses, a quantity of 40 or 50 c.c. During the following months, after the adjusting period is passed, he carries the total dose to 80 or 100 c.c., especially when the patient begins to improve. In these cases he continues the injections until he thinks the maximum dose has been obtained which is inferred when there is no longer any reaction to the doses. Of the eight cases reported in this paper improvement occurred in nearly all and in two cases there seemed to be a practical cure.

**36. School Hygiene.**—Chapin suggests various measures in school hygiene and in the way of instructing children in cleanliness and avoidance of everything that will produce disease. He says children should be taught: Not to spit; it is rarely necessary. To spit on a slate, floor or sidewalk is an abomination. Not to put the fingers into the mouth. Not to pick the nose. Not to wet the finger with saliva in turning the leaves of books. Not to put pencils into the mouth or moisten them with the lips. Not to put money into the mouth. Not to put pins into the mouth. Not to put anything into the mouth except food and drink. Not to swap apple cores, candy, chewing gum, half-eaten food, whistles, bean blowers or anything that is habitually put in the mouth. Teach the children to wash the hands and face often. See that they keep them clean. If a child is coming down with a communicable disease it is reasonable to believe that there is less chance of infecting persons and things if the hands and face are washed clean and not daubed with the secretions of the nose and mouth. Teach the children to turn the face aside when coughing and sneezing, if they are facing another person. Children should be taught that their bodies are their own private possessions, that personal cleanliness is a duty, that the mouth is for eating and speaking and should not be used as a pocket and the lips should not take the place of fingers."

**40. Urticaria of the Upper Respiratory Tract.**—The condition described in Somer's paper seems to be much the same as has been reported by various authorities as the faucial and pharyngeal manifestations of angioneurotic edema.

**41. Hematuria for Movable Kidney.**—In the case reported by Cabot there was a hematuria with symptoms which seemed to indicate that it was due to dragging on a movable kidney; it was apparently mitigated by a change of position, which relieved the dragging. The patient was finally cured by operation. He has studied the literature to find similar cases and finds but one which corresponds exactly in its description. It is plain, he says, that a kidney with short vessels will be quick to feel the effect of a downward pull. With a kidney lying unusually high, it is conceivable that this pull might produce considerable obstruction to the circulation before the organ came down low enough to be regarded as a movable kidney. Cases of hematuria are occasionally reported in which no cause can be discovered and in which cutting down upon the kidney and splitting the capsule effects a cure. He asks if some of these may not be instances of congestion from the unrecognized downward drag, which has been corrected by the adhesions following the incision into the kidney.

**43. Spinal Fracture.**—The following are the conclusions of Walton's article: 1. There are no symptoms which establish (otherwise than through their persistence) irremediable crush of the cord. 2. While total relaxed paralysis, anesthesia of abrupt demarcation, total loss of reflexes, retention, priapism and tympanites, if persistent, point to complete and incurable transverse lesion, the onset of such symptoms does not preclude a certain degree at least of restoration of function. 3. The prognosis without operation is grave. 4. While the results of operation are not brilliant, they are sufficiently encouraging to warrant us in making the practice more general. 5. In most cases it will be wise to operate within a few days of the injury; but a delay of some hours is advisable, partly on account of shock and partly to eliminate the diagnosis of simple distortion. 6. We have no infallible guide to the extent of the lesion. The operation, at the worst, does not materially endanger life nor affect unfavorably the course of the case, and may, at least, reveal the lesion and lessen the pain; it may sometimes save a patient from death or from helpless invalidism of the most distressing character. Instead of selecting the occasional case for operation, we should rather select the occasional case in which it is contra-indicated (the patient with great displacement of vertebrae, the patient with high and rising temperature, the patient plainly moribund, the patient still under profound shock). 7. The dura should be opened freely; it need not be sutured; drainage is not necessary.

52.—See abstract in THE JOURNAL, xxxvii, p. 934.

**59. Torsion of Arteries.**—The subject of MacFarlane's address is arterial torsion after hemorrhage, and he advocates it as expedient and effective. It will not absolutely prevent secondary hemorrhage, but it is, he believes, as effective as ligation, and in the Western Pennsylvania Hospital it is considered the best method for arresting hemorrhage. The rule is to perform torsion in all cases when not contra-indicated; oozing veins are treated in the same way. In most cases of amputation there were no ligatures or sutures except those of the flaps. Amputations contiguous to tissues that have undergone changes in chronic inflammation are mentioned with the probability that torsion will not suffice, but MacFarlane is rather inclined to believe in its efficiency even in these cases. He reports from the records of Dr. Murdoch showing a number of cases in which it has been used. In his own last term of service, in 17 cases there were 13 with 15 amputations of either the leg or thigh, one being a double amputation and another a second amputation in senile gangrene with atheromatous arteries. This last case died, being the only fatality. In all these cases hemorrhage was arrested by torsion, with the exception of the nutrient artery of the bone, which was plugged.

**60. Gout and Obesity.**—Anders calls attention to certain complications of these conditions such as a hyperemic type of bronchitis with troublesome cough, and frequently copious,

mucoid expectoration, which he finds especially in the anemic variety, associated with the phlegmatic temperament. Dyspnea is common in this type also, although it is not so frequent if the patient be plethoric. The bronchitis of anemic obesity runs a slow and often irregular course, unless the underlying causative condition is relieved. Closely connected with this variety of bronchitis and to some extent dependent upon it is asthma, the attacks usually occurring at night after hours of sleep, as they do from other causes, such as gastric disturbance. Its cause seems to be associated with the gouty diathesis and hepatic inadequacy. His own observation and experience lead him to think that the severe paroxysmal dyspnea seen in obesity is, in many cases, not a true asthma; and the attacks are often relieved by assuming the erect posture. Genuine asthma may occur, though less often than supposed. The question of the relation of asthma to polysarcia is somewhat obscure. His own tentative conclusions are: 1, that asthma occurs in about 5 per cent. of the cases of obesity; 2, that it only occurs in extreme polysarcia; 3, that a gouty state or history is found in most cases in which true asthma is secondary to obesity; 4, that about one-half of the cases are curable by overcoming the causative condition." The dry, chronic bronchitis of Laennec is recognized by most writers as a distinct variety of bronchitis due to the gouty state and is to be regarded as part of the general fibroid process in some cases. In conclusion he calls special attention to the form associated with hepatic and renal inadequacy and a highly acid urine; a type of lithemic bronchitis characterized by dry irritating cough with slight expectoration and no specially peculiar physical signs. Exacerbation may occur at any season of the year, depending upon fluctuations in the uricacidemia. The principal thing in the treatment of these cases is to recognize the cause and treat the lithemic state.

**61. Medical Examination in Marriage.**—Bateson maintains that a person should consider his health as a matter of entailment; that heredity should always be considered in marriage, hence the duty of everyone to consider the possibility of transmission of his own physical defects. It is evident that medical examination as an essential preliminary to marriage would be a great aid in preventing the production of defective human beings.

**63. Surgery in Neurasthenia.**—The various conditions of disease capable of surgical relief are noticed by Nutt, who wishes to emphasize the following points: 1. That there are many pathologic lesions of various organs, which, by nagging and goading the nerve centers, will sooner or later cause various neurotic disturbances called neurasthenia. This result often overshadows the original lesion which causes it. In order to fully appreciate and detect these reflex disturbances as we meet them in general practice, we must have more intimate knowledge of the abnormal conditions of all the organs. 3. That by restoring or correcting these diseased or displaced organs, the nervous symptoms will often promptly disappear. 4. That in another large class of neurotic patients with organic lesions, an important part of the treatment is to remove these lesions, in connection with the medical treatment necessary to restore the nerve function itself. 5. That knowing the effect of various diseased organs and anatomical lesions on the nerve centers, their early correction or repair would save years of invalidism and mental suffering to a large number of patients.

**72. Trachoma.**—Steiner describes, occurring in Malays, certain diffuse brown colorations with interspersed darker places extending from the cornea over the conjunctiva, and regular round black spots like ink, from the size of a pinhead to that of a pea, produced by trachoma. They have no pathologic importance, but if he followed the practice of some oculists in Europe of removing black spots from the conjunctiva to prevent the production of malignant tumors he would have to operate on about one in every ten Malay patients. Similar patches appear in other colored races. He has seen them in the Chinese and in one full-blooded Arabian.

**73. Carbon Bisulphid Poisoning.**—Heath reports a case

which he thinks is the second one in this country and describes the symptoms: headache, vertigo, irritable temper, nausea, ringing in the ears, replaced later by insomnia, low spirits, anesthesia and weakness. In advanced cases mental debility is observed. The eye symptoms may appear in the first stage, but the complaint of fogginess is most pronounced in the latter stage. The central visual acuity may be reduced to counting fingers at three meters or seeing only large type. There is generally pallor of the optic disc on its temporal half, though the fundus may be normal. The question whether it is a retrobulbar or axial neuritis or a lesion elsewhere is of interest, but he does not express a positive opinion. The prognosis is favorable and recovery rapid if only the early symptoms are experienced, but if mental and muscular weakness occur, permanent injury may be produced.

**75. Residual Sensations.**—Broughton criticises C. F. Cooke's test for diplopia with residual sensations and the measure of ocular muscle imbalance. Cooke's theory is that when one eye is closed, with relaxation of the levator palpebræ muscle, there is less tendency to fusion of images and the closed eye assumes its natural position more readily than when simply shielded by a screen. If the eye tends to deviate from its fellow there will be transient diplopia on opening and a second image of a candle-flame or a luminous point will be seen to merge quickly into the image seen by the other eye. Broughton has found this test very unreliable. The pressure exerted on the globe by the eyelids in the natural effort of closing one eye without the other is enough, in his opinion, to produce deviation in the axis of vision observed. He thinks such a statement as that of Cooke's is misleading and the article should not be passed without criticism.

**81. Epinephrin.**—Abel describes the method of producing this material and its behavior under different re-agents. He finds that the blood-pressure reducing constituent of the suprarenal gland can be isolated by his method in the formation of a basic, minutely crystalline though unstable compound which agrees in some of its properties with the substance he has called epinephrin while it fails to exhibit certain other qualities equally fundamental and characteristic. Mineral acids, however, easily convert this substance into one which is physiologically active and also gives all the characteristic reactions of epinephrin. Highly soluble and apparently stable salts of therapeutic and chemical importance are therefore easily made. Further analyses will soon be given showing the changes that take place under the influence of acids, how these new compounds agree with those of the former series described by the author and how far the substances isolated by zinc processes agree in composition with those similar and probably identical compounds contained in the material analyzed by Aldrich and Takamine.

**82. Bottini's Operation.**—Young describes a new instrument which differs from the Freudenberg apparatus by having interchangeable blades and other alterations such as the shape of the handle and beak. He thinks these are decided advantages, and reports a number of cases showing the working of this instrument. He calls attention to the special local examination which should be made with the catheter, finger and cystoscope to locate and diagnose the exact condition in the prostate and emphasizes the importance of employing the Bottini operation in accordance with the character of the prostatic obstruction as thus ascertained.

**83. The Anopheles of Baltimore.**—Hirschberg and Dohme give results of their investigation on waters and regions around Baltimore with special reference to the destruction of malaria-bearing mosquitoes. They find that two species breed there, one in the higher regions, the other in the lower and salty marshes. The distribution is such that they conclude the extermination of the mosquito is an impossibility and the prophylaxis of malaria will have to be confined to the careful screening of doors and windows and the protection by screens of persons already infected from mosquito malaria. The disease should also be reported to the board of health to enable them to take precautions.

**90. Bacteriology of Conjunctivitis.**—From a study of the subject, Jameson concludes: "1. That the etiology is probably not primarily bacteriologic. 2. That acute and more often chronic hyperemia of the conjunctiva is probably the exciting cause. 3. That the condition resulting from this vesicular derangement is a change in the fluid constituent of the conjunctival sac by the outpouring of sanguineous exudate from its impaired vessels. 4. That this in turn gives to organisms already existent in the sac, principally the staphylococcus epidermidis albus, a suitable nidus for rapid propagation. The normal equilibrium being immediately overthrown, diminished resistance, epithelial abrasion, altered secretion, and impaired irrigation antagonize and overpower the attributes the organ possesses of maintaining the sac in health."

**91. Brain Surgery.**—Barber reports several cases in which he opened the posterior cranial fossa in apparent tubercular disease with good results. In another case of ruptured cyst, in which drainage was instituted, the patient did not recover, although the symptoms were for a while somewhat relieved. He calls attention to the advantage of drainage in this most inferior portion of the cranium over puncture through the fontanels and direct drainage in the lateral ventricles. The natural position of the head in operation on the hind brain is all that is to be desired. It is possible that in tubercular cases the mere exposure of the diseased parts to the air may be of value, as in peritonitis. While his results have not been brilliant, still he has prolonged life and made it more durable.

**12. Tuberculosis.**—Lewis has studied the action of sputum inoculations in different stages in guinea-pigs and believes that the tubercle bacilli found in the late stage of pulmonary tuberculosis are more virulent than those found at the onset, though as yet he has not accumulated sufficient evidence to positively establish this point. He thinks the tubercle bacillus is evolutionary in character and that this evolution is evidenced by certain variations and gradations in a morphology and virulence modified by the chemie or biochemie conditions of different environments. We do not as yet know enough about the vital resistance or immunity. The cure of tuberculosis is as far in the distance as ever. He emphasizes the fact that development of tuberculosis in the individual is the result of coincidence not in one but in several conditions, viz.: 1. A potent tubercular infection depending for its potency on a certain degree of virulence. 2. A certain negative chemie or histologic condition of the lymph nodes, resulting from hereditary tendencies or from circumstances of environment, which fail to arrest or inhibit the growth and systemic ingress of potent tubercle bacilli. 3. A retrograde metamorphosis of structural cells in some part of the body, more particularly in the lung, from trophic, traumatic or toxic influence which favors the local growth of the invading germ. Thus a particularly large amount of a specific virulent tubercular infection might overcome resistant conditions and on the other hand, a weakened lymphatic system would be more vulnerable to a non-potent infection.

**103. Home Treatment of Tuberculosis.**—McGahan admits that the sanatorium furnishes the best results; but for the majority of patients who have to be treated at home he recommends certain rules. He suggests keeping the patient as much as possible out of doors, if necessary building a tent in the back yard or putting the bed on a balcony or roof. The disease should be recognized early to protect other members of the family and the patient's sleeping quarters must be isolated. The habit of kissing should be prohibited. The patient should rinse out his mouth with an antiseptic solution every day. All the necessary precautions for the protection of sputum should be carried out. Ventilation of the apartments in which the patient lives is emphasized and he should not be afraid of night air. Use a room with a fireplace instead of a stove. Proper feeding is as important as ventilation, and McGahan would give the patient as much nourishment as he can assimilate. It is well to give some hot drink in the morning on waking, before getting out of bed, such as a glass of hot milk,

cocoa or beef tea. This loosens the mucus and strengthens the patient. If the digestion permits it is wise to give three meals a day and also some light food between the meals and upon going to bed. But one should not overtax the digestive organs. He strives to have the patient take daily from one and a half to two gallons of milk and at least four eggs, cooked in any way except fried. Roast beef, beef steak, mutton, lamb, turkey or chicken with vegetables should be given with enough variety to tempt the appetite. Plain pudding or fruit may be allowed for dessert, but the eating of pastry should be discouraged. Alcohol is to be used only when the patient needs stimulation. While there is fever it is well to keep him in the reclining position, as in a reclining chair, but when the fever ceases exercise should be encouraged, especially to expand the chest, but fatigue must be avoided. There is no specific drug. Tonics may be used and he finds the best results from iron, strychnia, codain and arsenic. Cod-liver oil and malt are foods and when properly administered can be taken by any patient. The gastric function should be watched. Each form of tuberculosis must be treated according to the symptoms. Cough needs no treatment unless it disturbs the rest; in this case codain and heroin have served the best purpose. When the patient has had no fever for six months, cough has ceased and the tubercle bacilli are lacking in the sputum, we may consider him cured, but the patient should afterward live in good air, have plenty of it day and night and, if possible, follow an occupation that will keep him out of doors. In any case he should be watchful in regard to his health.

**107. Renal Tension.**—In this paper Dennis takes up the view of Reginald Harrison on the effects of renal tension and reports cases. He believes that attention should be directed to this element in the pathology of the kidney and the importance of considering the possibility of rendering surgical relief where medicine seems to fail.

**109. Tuberculosis.**—The advantages of the sanatorium treatment of tuberculosis are enumerated by Taylor and the corresponding difficulties of carrying on the same treatment at home. Co-operation and example of other patients and close medical supervision overcome the patient's prejudice and make him do what is best for himself.

**110. Tuberculosis.**—Greene believes that we should have a national board of health, with a cabinet officer at its head, to direct a national crusade against such diseases as tuberculosis. We should disseminate information in regard to this infection; insist on regulation, enforcement of laws against spitting in public conveyances and walks; demand frequent and thorough disinfection of sleeping cars, hotel apartments and public buildings, and the most rigid inspection of all meats and dairy products. There should also be provided sanatorium hospitals for the consumptive poor and societies should be formed for the enforcement of sanitary regulations and dissemination of information along the lines suggested.

**122. Psychiatry in the Twentieth Century.**—The conditions and treatment of the insane at the present time are reviewed by Hurd and historic facts referred to. He calls attention to the importance of the study of the pathology of the condition, the ineffectiveness of medical treatment, the need of better clinical studies, proper management and location of hospitals, special training for those who care for lunatics, the assumption of this care by the state, attention to the different classes of patients and doing away with the political management of insane hospitals. The last mentioned he calls one of the greatest evils of the day. As regards prophylaxis of insanity, he considers especially the injudicious use of alcohol and thinks we should have some efficient measures for controlling this evil. The importance of heredity should also be insisted upon and the public instructed accordingly so that the propagation of insanity may be checked.

**123. Interstitial Nephritis.**—Moriarta insists on the importance of hygiene, proper climate, a regular quiet outdoor life, regulated diet, and avoidance of uric-acid producing substances. A milk diet is admirable in cases of chronic uremia. He sees no objection to a limited amount of tea and coffee

when the kidneys are secreting a proper amount of fluids and solids; a light animal diet with vegetables and cereals is permissible. The amount of animal food depends upon each individual's condition. Alcoholic beverages may be in some cases a very grateful and necessary stimulant, but malt liquors are objectionable. A light wine with only a small percentage of alcohol is best. The secretion of urine should be carefully watched, and all these matters should be observed continuously. A few drugs, such as iodid of potassium, bichlorid of mercury or calomel in small continuous doses and tincture of muriate of iron, associated with the proper prophylactic measures are useful in these conditions of chronic nephritis before organic changes become marked. The cause of the condition should be considered, whether of syphilitic, gouty or metallic origin, and the treatment directed accordingly. When exacerbation occurs with mild uremic symptoms, the patient should go at once to bed and the bowels should be relieved by some saline cathartic, preceded or not by calomel as may be determined. While ventilation is necessary, chilling is to be avoided. A light diet should be at once instituted and a quantity of water given at regular intervals; hot water is best and ice water should be avoided. Cream of tartar water is useful when the secretion of urine is scanty and vapor baths are also serviceable. The condition of the heart and vessels should be ascertained, and when the attack does not clear up, urinary secretion keeps down and edema appears, we must act quickly; cardiac stimulants and drastic purgatives are of use. Elimination by the skin must be utilized as quickly as possible. If convulsions occur, chloroform should be inhaled, morphia given hypodermically and chloral by the rectum. If the right side of the heart is engorged, he believes a little blood-letting from the arm may be of use. The successful treatment of this condition requires that one should be familiar with the physiologic action of the remedies, in addition to the thorough appreciation of the pathological condition of the patient.

**132. Glaucoma.**—The lack of diagnosis of this condition and misdirected treatment and consequences are specially noticed by Rogers, who cautions against the indiscriminate use of atropin in eye diseases. He reports cases and says: "Always think of glaucoma when you look at an inflamed eye and then no mistake will be made." Mydriatics act badly by crowding the iris into the filtration angle and tend to block it, this increases the ocular tension and they may even thus produce glaucoma by their action.

**133. Pneumonia.**—The important features of the treatment of pneumonia are summarized by Chesebro as follows: "1. Place the patient under the most favorable hygienic conditions with special reference to ventilation. 2. Carefully regulate the diet, guarding against constipation and insisting upon the liberal use of pure, cool water. 3. Early in the course of the disease employ counter-irritants, particularly in the broncho-pneumonia of children. 4. Relieve distressing cough by inhalations and if necessary by the use of opium or its derivatives. 5. Relieve pleuritic pain by the intermittent use of hot or ice poultices or by the subcutaneous use of morphia. 6. Reduce temperature, if necessary, by bathing. 7. Stimulate heart with strychnin and in selected cases with alcohol, digitalis and normal salt solution. It is possible that venesection, which may be followed immediately by the injection of normal salt solution, is indicated in certain cases of engorged right heart and if boldly done may be instrumental in saving life. 8. Employ large and frequently repeated doses of antipneumococcal serum in desperate cases, particularly in those with a tendency to extension of the inflammatory process."

**143. Antidiphtheric Serum in Sepsis.**—Paton recommends the use of this drug by the mouth in cases of sepsis. He reviews the authorities to some extent to show the action of the gastric secretions upon antitoxin. He has given over 8,000,000 units of diphtheria antitoxin by the mouth during eight and one half years and claims that it proves the value of the method. The form in which he gives it is to add carmin 8 gr. to the ounce to the British pharmacopeia solution of tragacanth. The formula then runs:

Diphtheria antitoxin, 3000 units;  
Mucilag. tragacanth. carmin, q. s.;  
Aqua, q. s. ad f3iiss.

The dose usually given is half an ounce and varies from night and morning to every six hours, the latter only in exceptionally severe cases. For erysipelas half an ounce every eight hours is usually effectual. For acute peritonitis or appendicitis repeat the above dose in two hours, again four hours later and then in eight hours more. This usually does all that is required. Abscess when formed usually requires operation, but the use of antitoxin may relieve the constitutional symptoms and if employed in time may abort the abscess. For children the same dose may be given, but for small children one-half the dose is effective. In about one per cent. of the cases a little kidney irritation or skin eruption may be seen; both are only transitory.

**144. The Drug Habit.**—The method employed by Lott is the use of hyoscin in free doses. In the opium habit he gives nothing to move the bowels, for as soon as the opium is out of the system a bilious diarrhea sets in. The patient should have had his customary dose of opium an hour or so before beginning the treatment. Lott gives the patient about 1/100 of a grain of hyoscin hydrobromate and 1/20 of a grain of strychnia nitrate and repeats with 1/200 of a grain of hyoscin every thirty to forty-five minutes until he finds the amount that will affect the patient. When the dose is determined, it is administered about once an hour for forty-eight hours, never leaving the patient for a minute. In case of alcohol habit he begins with a purge of calomel and if the patient is not using morphia also he could be given a dose of that drug to quiet him at the beginning or during treatment. At the end of forty-eight hours' treatment with hyoscin the patient is allowed to come from under the remedy and will usually say he does not want any of his accustomed drink. Then Lott gives doses of pilocarpin, 1/8 gr. usually reinforced with strychnin nitrate, 1/20 of a grain every two to four hours. The mouth that has been so dry under the hyoscin begins to be wet and saliva abundant. The urine which has been scanty and high colored becomes abundant and clear and skin elimination is active. If the pilocarpin acts too freely a small dose of atropin 1/150 gr. will check it. The diarrhea, which is by this time annoying, is best controlled by doses of bismuth subgallate and the fluid extract of coto bark, 30 to 40 drops, four to six times a day. If the patient goes to sleep and sleeps from two to twenty-four hours he does not discontinue the hyoscin. The heart and respiration are carefully watched. When the patient comes out of his sleep he will probably be flighty, but will be easily managed. The after-treatment consists in building up the health, appetite, digestion and assimilation and regulating sleep. He reports cases to show that hyoscin can be utilized in this way with safety, giving the details of each dose.

**155. Creosote in Pneumonia.**—Van Zandt has been using carbonate of creosote since 1890 and has lost but one case; in this the drug was absolutely ineffective. He has seen one or two other instances where this drug has failed, but, as a rule, he thinks, a large percentage of pneumonia cases are shortened or aborted, almost all the rest are mitigated, while only a very small percentage are not at all affected by the remedy. He does not think calomel or guaiacol a proper substitute. He has been giving it in doses of 7.5 to 10 grains or minims every three hours. He never uses expectorants or nauseants, ordinarily only the carbonate of creosote without other medication. Occasionally strychnia with an anodyne in the beginning of painful cases is indicated.

**156. Infections.**—The conclusions of Hamilton's paper are as follows: "1. It is through the lymph channels, and not the blood vessels proper, that we get septicemia after pyogenic infection. 2. Where we have so-called pyemia or septic emboli lodged in other portions of the body, it always comes from the blood vessels after a certain amount of trauma. 3. A tubercular abscess is almost always distant from the site of infection and situated in the lymph nodes on the proximal side from the site of invasion. 4. Tubercular septicemia always

comes from the involved blood vessels and not through the lymph channels. 5. A typhoid infection differs in no respect from a pyogenic infection, except as it is altered by the structures involved. 6. The initial lesion of typhoid fever is sure to be in the bowel from the character of the lesion found in the gut. 7. Death from typhoid fever almost always comes either from typhoid septicemia or from perforation. 8. Septicemia from typhoid fever is more liable to occur than septicemia in a simple abscess, owing to the histologic structures involved and a milder form of infection, causing thereby less infiltration of leucocytes. 9. The site of infection with malaria is in the capillaries and its ravages are in the blood vessels; later symptoms are produced by the irritation of the germs on the capillary wall. 10. The pathological changes in smallpox are in the blood at first, and then transferred to the tissues, where the same pathological changes take place that we find in any pyogenic suppuration."

2. Varicose Veins.—The motif of Gould's lectures is that the varicose veins are more in the nature of superabundant development of venous tissue than the result of yielding of veins to excessive intravenous pressure. The following facts lead him to reject the obstruction theory: 1. The age at which varices are first noticed, before the individual growth is complete. The general condition of the patient, who is usually in robust health. The conspicuous absence in cases of varix of the usual symptoms and consequences of venous obstruction. The edema, induration and impairment of function are usually absent and the result of excision of varicose veins and also of the ligation of the main vein would be the most irrational procedure if obstruction were the cause; it would only cause further obstruction to the venous return, and yet there is no clinical fact better tested than the success of both these measures. The influence of pregnancy is also another point in favor of the angioma theory. Varicose veins often never trouble until pregnancy occurs, and while they may be caused by pressure from the pregnant uterus, it is to be remembered that, entirely apart from any pressure effects, pregnancy produces in some women quite remarkable vasomotor disturbances that are not necessarily the result of pressure of the enlarged uterus. The sex-incidence of varix is another point. There is no reason why man should be more liable than woman. On the obstruction theory we should expect to find the greatest sufferers among women, but the reverse is the case; leaving entirely out of the question varicocele, the number of men exceeds women by the proportion of three males to two females in his own statistics. Before saying why varicose veins are venous overgrowths, he thinks it is well to ask if there is any evidence that the growth of the veins of highly specialized structure ever occurs in the adolescent or adult life, and he reports cases which seem to him to indicate this possibility; that is, the occasional development in the adult of what may be classed as venous angioma. Admitting the possibility of such development, what evidence is there to support the view that varix is a form of this venous angioma? 1. In the first place, he says we occasionally meet with cases in which we have a combination of undoubted venous nevus and varix, and he notices instances. 2. The capricious irregular distribution of varices. Sometimes it is the whole saphena from the groin to the instep that is enlarged, the tributaries being intact; then it is a small section of the vein. The extreme irregularity and variation in the seat or extent of the affection seem to mark it out as overgrowth of the venous tissue, errors of development often showing such occurrence. Again, the early age at which varices develop is another interesting fact and their heredity is a recognized factor. The striking innocuousness of varicose veins is also in favor of this view. They persist quite unaltered for many years and certainly are much less troublesome in the latter than in the earlier years of early adult life. This fact is, he holds, more compatible with the view that they are exaggerations of a normal physiologic

structure rather than the result of pathologic processes. The last point he makes is the minute structure of varicose veins. It is often said that the walls of the varix, which may be very thick, are almost entirely of fibrous tissue, but that has not been his experience. There is usually also with the growth of the tissue a failure of the valve apparatus which has much to do with the production of the condition. The public have a very exaggerated notion of the gravity of varicose veins. He believes their effect on the nutrition of the part is very small and what is called varicose ulcer often occurs in perfection in limbs without significant varix. Its cause must be sought for elsewhere. The most frequent ill-effect is a sense of fullness of the whole part due to aching of the vein, caused by prolonged standing or walking, more frequently in hot climates. This is the only frequent ill-effect. Rarely we find a thrombosis in the varix, or still more rarely the vein bursts or is ulcerated into and causes hemorrhage. Where varicose veins do not trouble the patient he need not trouble himself about them, but in a young woman with large varices it is wise to have them treated before marriage and pregnancy. Young people of either sex ought to have them treated before going to live in a hot climate. He has employed of late the Trendelenburg operation in the treatment of these conditions. It has the advantage of being a simple procedure, rarely requiring more than five minutes. Gas and oxygen are often the only anesthetics needed. The saphena vein can readily be found by remembering that it lies a finger breadth to the inner side of the common femoral artery, the pulsation of which can be easily felt in the groin. He prefers to expose the vein by oblique incision from one and a half to two inches long, parallel with the fold of the groin and having its center over the vein. It is found between the two layers of the superficial fascia; it is cleared and a double ligature is placed on it, one thread being tied as high up as possible, the other about two inches lower down, the intervening portion of the vein is cut out. The wound is closed by a few points of suture and sealed by collodion dressing. The patient usually gets up on the eighth day and can leave the hospital two days later. He thinks it a simple and safe proceeding and one that is very useful in nearly all cases of varix, and frequently leads to shrinking or even disappearance of varices and exerts a strong influence in preventing thrombosis. Its good effects are most pronounced where regurgitations into superficial veins are most marked. "Its superiority to excision of varices is greatest in cases of widely distributed and numerous varicose veins, for it exerts its influence upon all the veins emptying into the saphena trunks. It is therefore useful in those widely distributed, even general, varicosities of the lower limbs for which excision is inapplicable. To ensure success the vein or veins must be obliterated quite at their junction with the deep veins. The fact that this operation has such a marked effect upon the course of varix is a strong proof of the important part that valvular defect plays in the history of cases of varicose veins."

**3. Premature Whitening of Hair.**—After reporting a case in which the hair turned white in four or five weeks in a paranoiac, Jones discusses the condition and gives statistics as to his observations in regard to the color of the hair in patients at the Claybury Asylum, and correlates the different types with different emotional conditions. He found light-haired persons were fond of amusement, while the dark-haired ones took more kindly to religious services. He thinks that whatever explanation is offered for the sudden blanching of the hair, which undoubtedly occasionally occurs, the close physiologic connection between the cerebrospinal axis and the skin, which have a common genealogy, must be borne in mind.

**4. Splenic Albuminuria.**—Rolleston has observed cases of splenic enlargement in which rest in bed or the recumbent position produced temporary albuminuria, which disappeared on resuming the erect position. He explains it on Falkenheim's suggestion that in the recumbent position the spleen presses on the left renal vein interfering with the return of venous blood from the kidney and this gives rise to albuminuria. It does not depend, however, on the size of the spleen, for it may be absent when the spleen is very large and was present

in two or three of his cases where the spleen was relatively small. It is possible that its occurrence or absence may depend on some condition such as elongation in the condition of the suspensory peritoneal ligaments of the spleen which thus determine or prevent direct pressure on the left renal vein, though anatomic evidence of this is wanting. It is also conceivable that the appearance of albuminuria is dependent on the underlying want of vitality or nutrition of the kidney, which, though not sufficient to induce albuminuria under ordinary conditions, causes it easily when chronic venous engorgement is superadded. In one of his patients albuminuria disappeared from the night urine after the patient had been some time in the hospital and had improved under treatment, and again after a slight attack of influenza the albuminuria reappeared. This hypostatic albuminuria is the reverse of what usually occurs in cyclic albuminuria, but it is possible there may be some cases of cyclic albuminuria in which the albuminuria appears when the patient is lying down and disappears when he is up. He has not, however, met with such a case, but its possibility is suggested by Edel's recent observation that a weak pulse and appearance of albuminuria in the urine in cyclic albuminuria are related and that regular muscular exertion, stopping short of fatigue and strengthening the heart's action, causes the urine to become free from albumin, lighter in color and more copious.

**6. Asylum Dysentery.**—Asylum dysentery, or colitis, which of late years has become a source of much anxiety to British asylum physicians, though not a new thing, has been recently treated by MacDonald by the injection of permanganate of potash. As soon as the case was diagnosed the lower bowel was washed out night and morning with a weak solution, 2 or 4 grains to the pint. The treatment rarely had to be prolonged beyond the third day and even the severer cases recovered. The drug appears to act in its double capacity as a disinfectant and styptic. Milk was not always a satisfactory diet. Mixtures of specially prepared beef tea and specially prepared rice with a liberal allowance of Port wine were largely used. He thinks the results of this method are worthy of being called to the attention of the profession.

**7. Feeding in Gastric Ulcer.**—In this clinical lecture Brunton notices the effects of different food substances on gastric ulcer, particularly the mechanical effects. He says: Supposing we had an ulcer of the back of the hand we would not be likely to treat it with sandpaper or vinegar and pepper instead of water. We should, therefore, avoid food containing hard seeds, small bones, vegetables containing cellulose which act as a brush, stringy meat, or anything that is hard and likely to block the pylorus. Increase of gastric acidity should always be avoided. The longer material stays in the stomach the more acid it is likely to become; hence, we should not feed too much at a time. While milk is an excellent food, yet it may be a stringy food, as he says, when given in large quantities. He mentions a case where a felt-like substance was produced in the stomach in this way. Mixture with lime-water will prevent its too rapid coagulation and its bad effect. There are many substances also that gastric juices alone affect very little, unless they are thoroughly masticated. By careful mastication we can prevent many of the troubles arising from irritating food in the stomach. We can not, however, depend too much on the patient's teeth. Recapitulating, he says: "In cases of gastric ulcer you begin by giving the patient rest in bed, with feeding by the rectum for a few days, then careful feeding by the mouth, while you still continue rectal feeding. The first food given is generally milk in small quantity, a tablespoonful of milk with a tablespoonful of lime-water every two hours. Gradually diminish the lime-water at the same time that you increase the proportion of milk, as the patient will bear it for several days more. Then you may try the effect of custard, which is very mild and non-irritating. Then you may give the patient pounded fish, and perhaps pounded chicken next day. You may give at the same time some chocolate, which I find is very well borne, and makes a great change in the patient's diet, which is otherwise very monotonous and tasteless. Then you will give some of the various foods, etc." In using starch it is important to

mix it up thoroughly and avoid lumps; this can be done by putting it in a little cold water first. The digestion of bread depends largely upon its subdivision and this is one advantage of stale bread, which powders instead of kneading up into a putty-like mass.

**11. Hernia.**—Brook describes a method of dealing with umbilical hernia to avoid the liability to recurrence met with in the ordinary operation where several lines of suture are placed directly over the other, thus making a weakest point which is liable to cause recurrence. He has adopted the following method in two cases of large pendulous irreducible and painful umbilical hernia in enormously stout women. "A long elliptical piece of skin, its long axis in the mid-line, is dissected off the tumor, care being taken to avoid buttonholing the sac where adherent to the skin. The sac is then isolated as far as the edges of the ring and opened by a transverse incision. The contents having been treated in the usual way, the peritoneum is detached all round and well within the ring, especially around the upper segment where the separation is extended at least 2.5 in. beyond the ring border. The two halves of the sac are then shaped into two flaps, each of which is a little wider, and about two inches longer than the diameter of the ring. The shape and size of the sac or accidental buttonholing may render it necessary to make these flaps right and left instead of upper and lower. In that case the sac will have been opened vertically instead of transversely. This was done in the first case. Through the free edge of each flap running sutures of fishing gut are now passed at intervals of  $1\frac{1}{2}$  in. or in the case of the upper which is destined to lie within the abdomen at shorter intervals. The ends of each suture are for the time being clamped together with pressure forceps. The two ends of the central suture of the upper flap are mounted on a large semi-circular perineum needle. The point of this, protected by the left forefinger, is carried through the ring and thrust from within out through the whole thickness of the belly wall at a point in the middle line about  $2\frac{1}{2}$  in. below the ring. The needle is withdrawn and the two ends again secured by a clamp on the surface. This is repeated with each suture of the upper flap, so that the row of double-ended sutures emerging from the skin forms about two-thirds of a circle whose center is a little below that of the ring. The sutures are now pulled up, care being taken that no overriding bowel is caught between the tightened edge and the parietal peritoneum, and the ends tied firmly together over a piece of lead wire bent to the required shape. The lower flap is now treated in the same way except that the needle with the successive sutures instead of being introduced into the abdominal cavity is made to penetrate the abdominal wall from the space around the upper segment of the ring which has already been prepared by more extensive separation of peritoneum at this point. These sutures are pulled up and secured in the same way as the others and the ring is closed by one or more rows of buried sutures." The result of this procedure is that the weak spot in the abdominal wall is backed by two thicknesses of peritoneum stretched straight and taut across it like a drumhead. He does not claim that this will remove all chances of recurrence, but he thinks it will diminish them. Two cases are not sufficient to draw conclusions from, but he hopes the evidence of its value will be provided by others. It has occurred to him that the same principle might be applied to inguinal and femoral hernia and he has since used it in four cases of the former and two of the latter. The following description of the operation applies to the inguinal variety: "The sac having been isolated from the cord, is cut across immediately above the part which it is intended to leave in the scrotum. A running silk suture is passed across it just above the point of section. The two ends of the suture are threaded on an aneurysm needle. The latter is introduced into the abdominal cavity through the sac, its point being kept in contact with the inner aspect of the wall till it reaches a point  $1\frac{1}{2}$  to 2 in. above and internal to the internal ring. Here a little pressure causes it to present beneath the skin. A small incision, one half to three-fourths of an inch in length, through skin and subcutaneous tissue exposes the point closely invested with a little process of peritoneum,

together with which it has been readily forced through muscles and aponeuroses. The peritoneum is nicked with the point of a knife, and the small hole slightly stretched with a sinus forceps, and aneurysm needle pushed through. The suture ends are now disengaged, the needle withdrawn, and by traction on the suture the sac is inverted and pulled well through. This is now twisted through one or two turns, the little process of parietal peritoneum pushed back with fine sinus forceps to its proper level, and the sac cut off and the stump fixed by one or two buried sutures. The other structures concerned in the hernia are dealt with by whatever method is preferred; personally, I adopt Bassini's where it is necessary to close them." This procedure does away with the necessity of slitting up the external oblique fascia roofing in the canal. This is a distinct gain where the canal has not been too unduly stretched or where there is no necessity for approximating the conjoined tendon to Poupart's ligament. The chief objections that may be urged are, that without exposing the site of the internal ring it is impossible to so thoroughly detach the neck of the sac from the transversalis fascia as to permit its being drawn sufficiently away from the position of the internal ring. In practice, however, the looseness of these attachments is surprising, allowing, as they do, complete and easy inversion of the sac. It may be objected that perforation of the peritoneum by the inverted sac may result in another weak spot. If, however, the perforation is situated in the muscular part of the wall (that is, through the rectus) and is made as small as possible, and chiefly by stretching rather than cutting, and is pushed well back after the sac has been drawn out so as to leave no funnel-shaped depression, he thinks this objection is more theoretical than practical. The same description suffices and the same arguments hold in case of femoral hernia, the sac being brought out above Poupart's ligament and  $1\frac{1}{2}$  in. outside the femoral ring.

**18. Operative Treatment of Non-Tubercular Chronic Nephritis.**—Rovsing has operated on nine aseptic and eight infectious cases of chronic nephritis. He is convinced that whenever there is pain, it is due to compression or stretching of the true capsule of the kidney. He agrees with Lennander that the renal parenchyma has no sensory nerves. This fact was demonstrated by study of kidneys sutured in the wound and also by his ability to operate on the renal parenchyma without narcosis. The capsule, on the other hand, is provided with sensory nerves from the lumbar and dorsal nerves. When it is compressed or stretched, it occasions a constant pain in the lumbar region, very different from the so-called kidney colic, which is in reality ureter colic and is always due to an obstacle preventing the free passage of the urine. Tumefaction and tension of the parenchyma may induce pain by stretching the capsule. The results of his 17 operations harmonize with these views, as in every instance as soon as the pressure was relieved, either by incising the kidney or evacuating an accumulation of pus or fluid, or detaching adhesions, the patients were relieved from their pains. One of his aseptic cases was a diffuse parenchymatous nephritis with intolerable pain in the upper portion of the kidney, palpable tumefaction, and a hematoma between the parenchyma and the capsule. The pains were relieved by mere evacuation of the hematoma. In another case a bilateral chronic glomerular nephritis had lasted for eight years, dating from a typhoid fever. The operation disclosed a perinephritic accumulation between the fatty and the true capsule. Acupuncture and excision of a small portion of the kidney tissue banished the pain. The albuminuria also ceased temporarily but returned later. The third patient was operated on for a suspected melanosarcoma as the cause of the hematuria from the left kidney noted by the cystoscope. The patient died the second day and both kidneys were found affected with diffuse hemorrhagic nephritis. Cystoscopy therefore may lead to a mistaken diagnosis, as in this case. It also shows that surgical intervention is dangerous in such cases, as, instead of arresting the hemorrhage, it is liable to induce violent hematuria, anemia and uremia. The results do not encourage intervention in any case of bilateral nephritis, even when restricted to merely incising the kidney. The fourth

patient was relieved of violent attacks of pain in the upper kidney region, by detaching a number of thick, fibrous adhesions. The kidney showed evidences of chronic nephritis from compression, suggested also by the preceding tedious hematuria. The kidney was incised and the intervention cured both the pains and the hematuria. In four other patients the interstitial nephritis and fibrous perinephritis observed evidently resulted from a uric or oxalic acid diathesis. The cases described in the literature as "nephralgia" or "hematuric nephralgia" probably belong in this category. His patients all suffered from paroxysmal attacks of pain in the kidney region. Hematuria usually accompanied these attacks, macroscopic or only to be detected with the microscope, which sometimes also revealed crystals of urates or oxalates. Under treatment of the uric or oxalic acid diathesis with mineral water or alkalies, the hematuria and the crystals may vanish, but the attacks of pain persist, thus demonstrating that they are not connected with the passage of crystals or sand. The operation will disclose adhesions between the capsule and the surrounding tissues and detachment of these will relieve the pain and cure both pain and hematuria. In one case of pains and hematuria a partial hydronephrosis was found in the upper portion of the kidney, due to compression by a cord-like vessel which ran across the rear surface of the kidney. All the disturbances ceased after this cord had been divided. Study of the eight infectious cases shows that the clinical and anatomic picture may be identical with that presented by the aseptic forms. It is therefore necessary to make a bacteriologic examination of the urine even when there are no symptoms but pure hematuria or nephritic albuminuria. Nephrolysis alone is sufficient in case of aseptic nephritis, with or without perinephritis. It puts an end completely to the pains and affords favorable conditions for the restoration to normal of the organ affected. Incision is unmistakably indicated in certain cases to open and drain a suppurating or congested region. Incision of the kidney seems to affect hematuria favorably when it is due to attenuated infection from the colon bacillus, while it is liable to prove dangerous in violent and virulent infections. In a case of the latter kind due to the staphylococcus aureus, he had to remove the kidney fourteen days later on account of excessive hemorrhage. His experience shows that chronic, infectious nephritis may be unilateral; also, that it may be restricted to a certain portion of the kidney; also, that a partial infectious nephritis may occur simultaneously in both kidneys. Infectious nephritis may resemble in every respect, clinically and anatomically, the familiar types of large white kidney, contracted kidney, etc.

**23. Chloroform in Heart Disease.**—In the discussion which followed Huchard's communication, reviewed in this department last week, the physicians and surgeons who took part agreed with the speaker that there is no more danger from chloroform in case of a compensated mitral defect than with the heart intact. Bucquoy ascribes death under chloroform to reflex action on the centers of respiration and circulation. The heart has little primarily to do with it. The majority of cases have occurred in subjects with sound hearts. Lucas-Championnière administers the anesthetic on this principle, starting with a few whiffs of ethyl bromid to deaden the reflexes. As soon as the mucosa feels numb, chloroform is substituted. Le Dentu remarked that Huchard's conclusions represent the average opinion of most surgeons nearly everywhere now, as it has been tentatively established of late. But he considers the prognosis of the anesthesia a little aggravated on the whole by the possibility of surprises during the anesthesia or of accidents later, which careful investigation will sometimes trace to alterations in the parenchyma of the heart. He urges closer study of the deaths that occur a few hours or days after the anesthesia, believing that they are due to the heart in many instances. He observed that cases of unsuspected heart disease are actual traps for the surgeon. He quoted Finney's experience in 142 narcoses on subjects with heart disease. He found that it was well borne in cases of valvular affections, while myocarditis required especial surveillance. Bucquoy and others called attention to the greater tendency to syncope and sudden death in cases of lesions of the aortic orifice.

**30. Pathogenic Unity of Dysentery.**—Moreul and Rieux found the bacterium isolated by Roger, in every case of dysentery, mild or severe, nostras or exotic, and always in much larger numbers than the associated bacteria. It resembles the colon bacillus, but does not produce indol from albuminoids. It has a specific agglutinating power and the serum of a horse immunized against it acquired bactericidal and antitoxic properties against it and its toxins. They have not yet applied the serum on man, but anticipate favorable results from its local application in a high intestinal injection. They appeal to persons living in localities where dysentery is endemic to cultivate and study this specific germ of dysentery.

**31. Otitic Origin of Asymmetry in Facial Expression.**—Lannois and Pautet noticed that in their experience unilateral slight facial paresis could always be traced to some lesion of the facial nerve from inflammation of the middle ear, sometimes long past and forgotten and sometimes recent.

**34. Difficulty of Differentiating Between Incipient Pulmonary Tuberculosis and Certain Localizations of Arthritis.**—Grasset is convinced that many cases of tuberculosis in the early stages supposed to be cured by sanatorium treatment were in reality merely the pseudo-tuberculosis which he describes. The arthritic diathesis generates auto-intoxication, and this in turn may induce a proliferation of tissue, especially of connective tissue, at points naturally weak or temporarily injured by the morbid products. The infiltration of connective tissue may happen to locate in the apex; the lung tissue becomes solidified and false membranes form on the pleura. This is particularly liable to occur, Grasset thinks, when some cutaneous manifestation of the arthritis has been cured too rapidly by external maneuvers or has suddenly healed. The pulmonary lesion simulates all the signs of incipient tuberculosis, and there is in addition, in many cases, a pain in the supraclavicular fossa during efforts at defecation. A concomitant bronchitis may still further obscure the diagnosis and the sputa even may be blood streaked, especially in young girls. Tuberculin would decide the question, but he considers this too dangerous a procedure for general use. He has witnessed very grave accidents from its use. More than this, he adds, every toxin in subcutaneous injection causes a congestion at the points of weakened resistance and may thus add to the signs in the lungs. The personal and hereditary history is most important for the diagnosis and the urine is always more acid in neuro-arthritic subjects than in those predisposed to tuberculosis. Arthritis may be due to an excess of assimilation or to insufficiency of disassimilation. In the subjects predisposed to tuberculosis, on the other hand, the assimilation is defective and disassimilation is excessive. Consequently, the treatment adapted to one class is directly injurious in the other.

**35. Strict Milk Diet for Adults.**—Lépine remarks that the physician can make his patients take on or lose flesh and can strengthen or debilitate them on a milk diet. This is possible when the composition of the milk is known. The dynamic value of the milk should be determined, bearing in mind that 1 gm. of proteids produces about 9 calories; 1 gm. of fats more than 5, and 1 gm. of sugar or starch about 4. The chief advantage of the milk diet is that it does not stimulate nor excite the mucosa of the digestive organs. It is therefore especially valuable in certain diarrheas and dysenteries. In liver affections milk is also useful, but it should be skimmed and diluted with an alkaline water in case of icterus. If preferred sweetened in such cases, glucose, or some other carbohydrate is preferable to cane sugar on account of the levulose formed from the latter.

**37. History of Gelatin as a Hemostatic.**—Miwa quotes the works of a Chinese physician dating from 204 to 219 A. D., in which gelatin is recommended as a hemostatic for all kinds of hemorrhage. It has been in use ever since for this purpose in China and for a thousand years in Japan. It was applied in an aqueous solution or as a powder, usually combined with other substances. It also enjoyed a reputation as a regenerator of the blood.

**38. Proposed Operative Treatment of Sciatica.**—Baracz has been studying Fajersztajn's "crossed sciatic sign." When the leg is flexed, the hip can also be flexed without pain in cases of sciatica, but if the leg be held straight, flexing the thigh is very painful. He called attention to the fact that flexing the sound thigh with the leg straight on the sound side, causes the same pain on the affected side. Pulling on the sound nerve draws on the diseased nerve and induces the pain, especially in case of adhesions at or near the emerging points of either or both sciatic nerves. Such adhesions are liable to form after inflammatory processes, and Baracz thinks that it may be possible to cure certain obstinate cases of sciatica by attacking the emerging point itself, instead of the nerve farther down. He therefore proposes as an improvement over the usual method of stretching the sciatic nerve, to expose it at its emerging point, detach all the adhesions found in or near the foramen, and stretch the nerve or not, as deemed advisable.

**39. Renal Colic, Renal Hemorrhage and Nephritis.**—Israel replies to Senator's article on this subject, of which an abstract was published in this department last week, that his intervention, incision or splitting the kidney, was successful in all but 2 out of his 11 surviving patients. Six have been permanently delivered from their pains and hemorrhages. In the seventh case they vanished completely on the side affected, but have since recurred on the other side, showing that the affection must have been bilateral. In 2 other cases the pains were banished for twelve and eighteen months, but then returned. The intervention was thus able to free 9 out of 11 persons after the failure of every known medical measure. On the other hand, 3 out of the 14 operated on have died. When we are able to diagnose with certainty beforehand and exclude severe bilateral nephritis, the intervention—limited to mere incision—will be so insignificant that the possible danger will be minimal and the advantages to be gained far outweigh it. The traumatic irritation from the incision may have a favorable influence in accelerating the retrogression of a chronic inflammatory process in the same way as we inject an irritating substance into a chronic synovitis. He found evidences of an inflammatory process in 85.4 per cent. of his 14 and 2 later observed cases, although the microscope was required for its verification in a few. He thinks that time and experience have amply confirmed his assertion that certain cases of renal colic and hemorrhage are the consequences of chronic inflammatory processes in the kidney and that these processes can be induced to heal by incision of the organ. He noted adhesions between the renal capsules and adjoining parts only in a few of his cases and observes that such adhesions do not cause pains unless they fasten the kidney in an abnormal position and thus hinder the outflow. Formation of adhesions is one of the aims of nephropexy. [In the general discussion of the subject in the Society for Internal Medicine, reported in the same number of the *Wochenschrift*, Klemperer, Casper and Zondek cited numerous cases bearing on the points discussed. The latter thinks that an angioneurotic origin for the hemorrhage should not be advanced until the entire kidney and ureter down to the bladder have been thoroughly examined for hidden calculi. Senator reiterated that incision of the kidney is an important progress as a means of diagnosis, but is never indicated as a therapeutic measure except in cases of threatening anuria, whether the latter be the result of some palpable obstacle to the flow of urine or the consequence of violent inflammation and swelling of the renal pelvis.—Ed.]

**40. Albuminuria Induced by Massage in Nephritis.**—Ekgren reports tests which demonstrate that the albuminuria increased very much in patients with nephritis under the influence of general massage. The elimination of albumin through the kidneys is more or less of an irritation for the organ, and consequently general massage should be ordered very cautiously in cases of nephritis. He found, also, that gymnastic exercises of the legs and arms had a somewhat similar effect in increasing the albuminuria, equally marked when the exercises were restricted to the arms alone. The body seemed to become accustomed to the effect of the massage in time.

**41. Etiology and Treatment of Pruritus Vulvae.**—Seeligmann has been able to isolate and cultivate a diplococcus from all his cases of pruritus vulvae during the last ten years. It resembles the gonococcus, but takes the Gram stain and differs also in its method of growth. He found that 10 per cent. guaiacol vasogen killed the cultures of the diplococcus in five minutes, which confirmed the almost invariable success of this salve in his clinical experience. He has the vasogen applied on cotton at night, repeated for several evenings if necessary, and has thus succeeded in curing many cases of secondary and primary true pruritus. If the 10 per cent. strength of the guaiacol vasogen is not sufficient, he uses a 15 or 20 per cent., but avoids this when possible, as it is liable to irritate. If the pruritus returns later, one or two applications of the vasogen will usually dispel it.

**42. Surgical Treatment of Lung Disease.**—Quinke claims that non-tubercular pus pockets in the lungs should be operated on early and not be allowed to pass into the chronic stage. The duration of the lesion is more important than the presence or absence of putridity, which is merely a secondary symptom that may appear and disappear. An abscess that forms around a foreign body is almost invariably putrid, and its removal is urgent even without a definite diagnosis. (See *THE JOURNAL* of December 28, 1901.) In most of the cases on record the foreign body was not found at the time of the intervention, and was expelled or coughed up later. In case of tuberculosis, nothing is accomplished by merely opening up the cavity. Such an abscess has no chance of healing unless the walls of the thorax over it are rendered flexible by resection of a portion of a rib. The walls of the abscess, disseminated with tubercles, have not sufficient vitality for any task beyond that of elimination and encapsulation of the focus. These processes can be materially promoted by relieving the tension, which relatively immobilizes the lung beneath. The favorable effect of such relief from participation in the movements of breathing is shown in cases of compression of a tubercular lung by a pleural effusion or pneumothorax, which sometimes arrests the disease process. It is possible that the improvement which often follows a pregnancy or a rest cure may be due to the more superficial breathing. Evacuation of the pus is of far less importance for the healing of a tubercular focus than the immobilization of the part. Bier and C. Spengler have reported great improvement after resection of the rib, without entering the focus. The latter has a patient permanently cured for twelve years by this procedure. He has performed it a number of times and resects at least 20 to 25 cm. of the rib, close to the spine. He attributes his success in great part to concomitant measures, especially inhalation of a substance to keep the air passages sterile. In the diagnosis of a tubercular lesion, the location and size of the cavity are of less moment than to determine whether it is circumscribed, unilateral or restricted to the upper lobe alone. In the latter case immobilization of the lung by thoracoplasty may lead to the encapsulating and healing of the tubercular focus.

**43. Surgical Treatment of Lung Disease.**—In case of a single, circumscribed focus in the lung, with fair general condition, Garré opens it up widely and drains or tampons if there are evidences of stagnating secretions and febrile septic manifestations. He opens up extensively and resects the infiltrated portion of the lung tissue with ample thoracoplasty in the rare cases of isolated cavities and tubercular foci in the lower lobe. He advocates mobilization of the thorax wall and pleura in case of a single established cavity in the apex. It can be accomplished by resection of the first three ribs without opening the pleura, or by resection of the second rib with pleurotomy and detachment of the adherent apex, or by an artificial pneumothorax, according to Murphy. About 96 cases of actinomycosis have been operated on according to the records, and 87 per cent. have been cured; 122 cases of gangrene of the lungs with 66 per cent. cured. Only 20 to 25 per cent. recover under internal treatment. In 57 cases of bronchiectasia, 46 were cured. In 34 cases of a tubercular focus the cavity was drained, but without much effect on the course of the disease. He urges

that operative intervention should be performed in case of bronchiectasia before the transition into the chronic stage. Only 25 per cent. of the echinococcus cysts treated by puncture alone recovered, while 90 per cent. of 79 cases treated by incision and evacuation were cured. The large proportion of recoveries in these various interventions demonstrates that pneumotomy in itself is not a dangerous operation. There are about 400 on record and 300 of the patients were cured from their ills.

**44. Operative Treatment of Gangrene of the Lungs.**—Lenhartz reports 23 cases of gangrene of the lung treated by resection of ribs and pneumotomy. There has been complete and permanent recovery in 11; 3 have died since from tuberculosis, 3 from sepsis and 1 from general debility. He operates in two sittings, as it is impossible to suture the pleura, and union has to be accomplished by vigorous compression. He warns against exploratory puncture. It entailed empyema in at least one of his cases.

**47. Attempts to Disinfect the Small Intestine in Man.**—Mieczowski utilized the opportunity afforded by several intestinal fistulæ at Mikulicz's clinic to study the action of various disinfectants. He found that the pure juice of the small intestine had no bactericidal action. Of various disinfectants ingested per os, menthol displayed a weak disinfecting power when it reached the intestine. Ictol and bismuth proved entirely negative. The one test with tannopin showed that the bacteria were reduced from 160,000 to 21,000 in twenty-four hours and to 16,000 in forty-eight.

**51. Histogenetic and Comparative Study of Malignant Tumors.**—Among the facts cited by Disselhorst is that in 262 cases Fröhner never noted carcinoma in dogs under 2 years of age. About 87 per cent. were more than 5 and 54 per cent. more than 7 years old. Malignant tumors are not rare in herbivorous animals. They have been found in dogs as 4.7 per cent. of all diseases; in cattle in 2 per cent., and in horses in 1.3 per cent. Sarcomata predominate in horses and cattle, carcinomata in dogs. In the latter, carcinomata form clinically 40 and anatomically 52 per cent. of all tumors; in horses sarcomata form clinically 21 and anatomically 47 per cent. of all tumors, and the proportion in cattle is respectively 27 and 37, while for carcinomata it is only 2.7 and 8 per cent. These figures are based on 86,113 horses, 85,537 dogs and 4972 cattle, treated at the Berlin, Munich and Dresden veterinary colleges. An interesting fact noted was that the percentage of malignant tumors among horses at Berlin was only .9, while at Munich it was 2.1 and at Dresden 2.5 per cent.

**53. Ambulant Treatment of Tubercular Joint Disease of the Legs.**—Wagner considers Helsing's glue bandage under the fixation apparatus the ideal combination for ambulant treatment of joint affections of tubercular origin. He follows Helsing's instructions as proclaimed in his recent work "Der Kriessapparat." One of the principal advantages of this combination is that the apparatus can be removed and the patient take salt baths while the limb is still immobilized in the glue bandage.

**54. Position of Patient in Operating on Biliary Passages.**—Berndt places a hard bolster, 12 to 15 cm. in diameter, under the back of his patient in the dorsal decubitus, beneath the last thoracic and the first lumbar vertebra. This enlarges the field of operation in a most surprising manner in all interventions on the biliary passages.

**56. Ergotin as a Prophylactic and Specific in Puerperal Fever.**—Solt points out that as the uterus contracts under the influence of ergotin, the walls become thicker, harder, the lumen of the vessels is partially or entirely closed and the surface becomes drier. This change offers far less favorable conditions for bacterial invasion than when the walls are soft and moist and all the blood and lymph vessels are gaping. Micro-organisms find it more difficult to penetrate the walls of the uterus and pass into the general circulation, and a rampart is thus interposed between a focus in the uterus and the rest of the organism, and between a focus in the vagina, rectum or perineum and the uterus. Hager recommends ergotin as a

means of forestalling absorption of purulent matters and Solt makes a routine practice of administering it in every affection inducing inflammation and suppuration, in cases of infected wounds, phlegmons, etc., with pyemic and septicemic symptoms. He gives ergotin instead of alcohol, and the stimulating effect is so pronounced that the patients ask for it. He recommends it internally before all operations on feeble patients, on account of its tonic properties. He has administered it in 30 cases of puerperal fever in the last seven years, and never lost a patient except one from an intercurrent dysentery. When the birth is proceeding normally, he gives two or three powders a day of .6 ergot until six have been taken, and has never known puerperal fever to develop after this prophylactic measure. In case of uterine hemorrhage, he supplements it by rectal injections of cool salt solution, with one teaspoonful of salt to the liter, or fresh milk with half the amount of salt. The uterus seems to contract with exceptional vigor under the influence of the milk injections. Rectal injections have more effect on the uterus than vaginal. After an operation, when the pulse or temperature is suspicious, he administers ten to twenty drops three times a day of a mixture of 5 gm. each of ergotin and distilled water, in 15 gm. of tincturæ amaræ. Another formula is 5 gm. ergotin to 20 of aq. menthæ pip. This is equivalent to about .1 to .18 of extract of ergot to the dose. He has witnessed chronic headaches vanish under systematic treatment with ergot. It has also proved effective as an adjuvant to the bromids in epilepsy, and has relieved the cough in recent laryngeal catarrh better than narcotics.

**62. Disinfecting Soaps.**—Tonzig's tests in regard to the disinfecting power of medicated soaps have convinced him that the only benefit to be derived from them is the pecuniary profits for the manufacturers. He devoted his attention mostly to the creolin soaps and found that the disinfecting power of the creolin was neutralized in its combination with the soap.

**63. Carbolic Treatment of Septic Processes.**—Chlumsky thinks that Phelps' method of applying pure carbolic acid to infected wounds and septic processes is rather too heroic. He calls attention to his somewhat similar but less dangerous practice of pouring into the wound a mixture of equal parts of pure carbolic acid and camphor. The oily fluid is not wiped off and is merely covered with gauze and oiled silk. It does not corrode when poured on the hand, and he has never observed any symptoms of intoxication, although he has used it extensively in more than fifty cases of erysipelas and infected wounds. He is convinced that the erysipelas yields much more rapidly under this than with any other treatment he has ever tried. It has proved equally effective in reducing the temperature in cases of infected wounds. The carbolic odor is masked by that of the camphor.

**64. Radical Operation of Hypertrophied Prostate.**—Roth reports twelve cases of hypertrophied prostate operated on by Bottini's method, with 9 patients cured, one improved, one unaffected and one death. The only contra-indications he admits are affections of the renal parenchyma in an advanced stage, and cachexia. He has operated in mild cases of nephritis without aggravation of the renal process. His patients were between 52 and 76 years of age. He advocates early intervention without waiting for complications to develop by wasting time on palliative measures.

**65. Phlegmon Around Hernia.**—Lottheissen adds three cases to the two reported by Nicoladoni in which a phlegmon developed around and outside of an old, easily reduced hernia. The patients were between 40 and 74, three men and two women. Suddenly, for some reason, the hernia became irreducible and symptoms of inflammation developed. The symptoms differ from those observed when the appendix is included in the hernia, as in the latter case the syndrome is more that of incarceration. The treatment can be only the incision of the perihernious phlegmon. It is perhaps wiser to postpone the incision of the sac to a second operation. As there are no symptoms of incarceration, delay is possible. When the phlegmon is healed the hernia should be cured in order to prevent recurrence of the trouble. One of Nicoladoni's patients

had a recurrence of the phlegmon, probably from a repetition of the same cause.

**66. Osteoplastic Trephining of the Skull on Account of Brain Tumors.**—Gussenbauer reports ten cases from his clinic and seven in private practice in which he attempted to remove a brain tumor by trephining. The wound healed by primary union in every case, and only one death could be ascribed to the operation. This was due to after-hemorrhage induced by excessive restlessness of the patient. Another patient died ten days later from pneumonia. In every case the headache was relieved and choked disc subsided temporarily or permanently, thus improving the sight unless amaurosis was complete. The motor and sensory disturbances in the face and limbs were also partially relieved. Contralateral paralysis frequently appeared after the operation, but was always transient except when due to extensive removal of the cortical motor regions. He uses the Gigli wire saw and the chisel, cutting the bone slanting. His experiences are described in detail. They harmonize in general with those of others, confirming the difficulty of curing the patient by the removal of a brain tumor, even in cases in which localized symptoms indicate a focus in the motor region of the central convolutions. Well-marked focal symptoms indicate that the region in question is diseased, but not necessarily the existence of a tumor in the strictest sense of the word. Focal symptoms in the motor zone of the central convolutions may prove to be merely the effects at a distance of a deep-seated tumor, as in one case he describes. In one of his cases there was recurrence of a gliosarcoma in three years. The two cases of tumors in the cerebellum in which the diagnosis was confirmed postmortem, had none of the symptoms imputed to such tumors. Gussenbauer consequently refrained from opening the cerebellum. Eight of the patients are still living. Comparative improvement is noted in several. Relief from the headache was the only result in one case. A good effect was attained in one syphilitic patient. The blindness returned after temporary relief in two or three and there has been a discharge of cerebrospinal fluid from the nose in several. None of the patients can be called fully restored. The article is concluded from the two preceding numbers.

**67. Thiosinamin in the Treatment of Cicatricial Stenosis of the Esophagus.**—Teleky is assistant in A. Fraenkel's Allg. Poliklinik, and reports a number of cases of cicatricial stenosis of the esophagus the result of drinking a caustic. When they were absolutely impermeable, von Hebra injected a solution of thiosinamin, which has a marked effect in softening cicatricial tissue by favoring the flow of lymph. The results were surprisingly satisfactory in some cases, although not in others, and study of the details shows that the drug has a marked softening effect on old cicatricial tissue. Recent cicatrices are loosened at first and then swell. Newly formed cicatricial tissue breaks up completely under its influence. This was shown most conclusively in one case in which a healed gastric fistula became loosened and the stomach wall separated from the abdomen under the influence of the thiosinamin which was being administered to render the stenosis of the esophagus permeable. The result was fatal to the patient. In comparatively recent cicatricial stenosis, the effect at first was marked improvement, but this was soon followed by a swelling of the parts and consequent aggravation of the preceding condition. In two cases in which the cicatricial tissue was several years old, the patients were permanently relieved from their previous ills and could eat and swallow with ease, the esophagus becoming permeable for a 21 sound. Hebra has distinctly warned against the application of this drug in all cases of partially healed tubercular or other foci. He has witnessed cases in which the cicatricial encapsulation was loosened and the process fanned into a flame by its administration. He also points out that its action in driving the lymph through the tissues favors metastasis of malignant tumors. It also has an unfavorable effect on all inflammatory processes for the same reason, especially those in the eye. Old cicatricial tissue in the eye, on the other hand, has been loosened and vision much improved in a number of cases in his experience. It merely loosens the tissue and renders it elastic, so that mechanical stretching,

previously impossible, can then be accomplished. Active movements of a joint after the cicatricial tissue has been loosened accomplish this purpose, as does also the passage of food in the esophagus and progressive sounding.

**68. A German Precursor of Harvey.**—Landau attributes the discovery of the circulation of the blood to Helvicus Dietericus, a prominent German physician who died in 1655. In 1622 he suggested the possibility of the circulation of the blood as he observed it in dogs, to his teacher, Caspar Hofmann, but the latter ridiculed the idea, and Dietericus did not insist.

**69. Was Cleopatra of Egypt a Physician?**—Zervos has unearthed old documents to prove that Cleopatra was the author of several works on medical subjects. They show a thorough understanding of the theme, he remarks, rare powers of observation and enviable conciseness of statement. Her "De Morbis Mulierum" includes good descriptions of "phlegmons of the uterus," displacements, etc. She observes that hemorrhoids are rare in women, but processes resembling them are frequent in the cervix. She lived at the time the Alexandria school was at the zenith of its fame and may have taken a medical course there. It only required six months. She killed herself, according to Galen, in the most scientific manner by having the asp's poison poured into a wound in her arm. She also embalmed Antony's body with a dexterity showing great anatomical knowledge. Zervos refers also to several Latin works dating from 1586, 1597 and 1612, which quote from her writings.

**71. Softening of the Brain Around Certain Tumors.**—Pellizi describes the clinical and postmortem observation of a tumor in the frontal lobe surrounded by extensive softening. The vessels seemed to be normal in the vicinity of the tumor and the softening was too extensive to be due solely to compression by the tumor. He attributes it to the pressure of the cerebrospinal fluid which was under very high tension. The white brain matter was not able to resist the pressure and gradually became compressed, softened and destroyed.

**72. Serum Therapy.**—This is the address delivered by Behring as the recipient of one of the Nobel prizes. The main points were mentioned in THE JOURNAL of January 4, p. 45.

**74. Neuralgia of the Sympathetic.**—Buch examines the patient in the dorsal decubitus when he surmises hyperesthesia of the sympathetic nerve. The abdominal aortic and superior and inferior hypogastric plexuses are particularly valuable for this purpose, as they can be compressed against the spine and are thus easily irritated, while the resulting pain can not be ascribed to any organ. In the physiologic condition the sympathetic is not sensitive, but when it is irritated the pain resembles somewhat labor pains, or dull colic, accompanied sometimes by other pains which have the character of surface pains, smarting, burning or cutting, etc. There are frequently pulsating pains and girdle sensations. Pyrosis may be sometimes induced by pressure on the hyperalgesic lumbar sympathetic. The radiating pains in stenocardia, gastralgia and enteralgia and many of the morbid sensations of neurasthenic and hysterical patients are due to hyperesthesia of the sympathetic. When pressure on the sympathetic reproduces the spontaneous attack, the diagnosis is certain. The cases are especially interesting in which the entire symptom-complex accompanying a gastralgia, for instance, can be reproduced by irritating the sympathetic. It is sometimes possible to abolish temporarily or permanently the entire syndrome by a single subcutaneous injection of antipyrin. Neuralgic symptoms involving the spinal nerves and headache from radiation of pain from the cervical sympathetic are among the most common manifestations of hyperesthesia of the sympathetic.

**75. Acute and Chronic Forms of Malignant Endocarditis.**—Thue attributes not only the fulminating but the insidious chronic cases of malignant endocarditis to pyemia. The infectious agent in the blood is therefore the necessary factor in all the various forms. He describes 5 acute cases in detail, including two that occurred in the course of a severe pneumonia, the pneumococci being numerous in the blood. The others were due to the streptococcus. He also describes 4 cases of the chronic form which show that there is no longer cause

for a sharp distinction between benign and malignant endocarditis, between the ulcerative and the verrucous—all are merely various phases of the same process. The chronic cases ran a course of four and one-half to eighteen months, fever alternating with long afebrile periods. The temperature curve was irregular even when within normal limits. Auscultation showed that the affection was unmistakably progressive. Frémissement was noted in one case. One patient had a history of articular rheumatism, and one of endarteritis with atheromatous degeneration. The joints were not affected in any of the cases, but in two there was an acute hemorrhagic nephritis with hemorrhagic pemphigus and herpes. In the other patients there were no symptoms on the part of the kidneys or skin, but one exhibited a hemorrhagic pleuritis, becoming later purely serous, with a hemorrhagic infarct in the lung. All the patients presented an extremely anemic aspect. No cultures could be derived from the blood during life in either of the cases, but the staphylococcus aureus was found numerous in the endocarditic processes in one and an indeterminate bacterium in the other two cases in which autopsy was permitted. Three of the patients were men between 21 and 50, the fourth a boy of 9.

**76. Sedimentation Process for Study of Sputum.**—Quensel adds to the sputum to be examined an equal quantity of a fluid composed of equal parts of 25 per cent. formalin and of 95 per cent. alcohol. The vessel should be of the capacity of about 200 c.c. The mixture is then concentrated in a centrifuge or shaken vigorously for a minute or two and set aside to settle in a conical glass. The sediment is then ready to stain. He uses anilin gentian-violet, decolorizing with hydrochloric acid and alcohol. The elastic fibers can be differentiated in addition by supplementing the above with Weigert's stain in which the specimen is left for twenty to thirty minutes and then decolorized as before, and restained with auramin.

## Queries and Minor Notes.

### DUCTLESS GLANDS.

BINGHAMTON, N. Y., March 14, 1902.

*To the Editor:*—Please give briefly the latest accepted views or teachings of the physiology of the thyroid, thymus, spleen and suprarenal glands; also what diseases or marked changes may be ascribed to a change in their functions. M. H. J.

*Ans.*—The thyroid is a ductless gland, secreting, by way of the lymphatics, a complex proteid containing iodine, to which the name thyro-iodine has been given. Administration of the thyro-iodine or the fresh gland causes a decline in body weight and toxic symptoms, such as tachycardia, vertigo and glycosuria. Degeneration, absence or extirpation of the thyroid causes cretinism and myxedema.

The suprarenal is another ductless gland with an internal secretion, the active principle of which has been isolated and called epinephrin by Abel, and adrenalin by Takamine. It stimulates the muscle-fibers of the arteries and heart. Applied locally to the mucous membrane of the nostril or eye, for instance, it causes a temporary contraction of the blood vessels and pallor. Removal of these bodies from animals is followed by death. Change in the suprarenals would accordingly interfere with the tonicity of the vascular system.

The splenic functions appear to be the following: 1. The development of white blood corpuscles; also red blood corpuscles during and shortly after fetal life. 2. Storing up of some proteid food to be introduced later into the blood. 3. From the presence of uric acid, xanthin, hypoxanthin and leucin, it is probably engaged in other nitrogenous metabolism.

The thymus diminishes after the second year, until scarcely a vestige remains. It is supposed to be a source of colorless corpuscles, and possibly colored corpuscles, in early life. From the presence of xanthin, hypoxanthin, leucin and other nitrogenous compounds, it may have other functions similar to those of the spleen.

### THE AUTOMOBILE.

CHICAGO, March 11, 1902.

*To the Editor:*—Last year, at this season, there appeared in THE JOURNAL several communications relative to the practicability of the automobile for physicians' use. There was considerable diversity of opinion regarding the best motive power; some claimed electricity, others gasoline and steam. No doubt the past year's experience of those using automobiles would prove valuable. As an intending purchaser, I would appreciate the information any reader may be able to give, particularly with reference to the method of propulsion. Yours respectfully, D. C.

### New Patents.

- Patents of interest to physicians, etc., Feb. 18 and 25.  
 693,487. Stethoscope. Robert C. M. Bowles, Boston, Mass.  
 693,637. Filler for capsules, wafers, etc. Arthur E. Brethour, Ottawa, Can.  
 693,587. Insufflator. Eugenia C. Campbell, San Francisco, Cal.  
 693,795. Respiratory apparatus. Erich Gliersberg, Berlin, Germany.  
 693,606. Hernial truss. Andrew Hunter, San Francisco, Cal.  
 693,554. Scarificator for surgical use. Lewis G. Langstaff, Brooklyn, N. Y.  
 33,749. Design, surgical rubber pad. Wm. P. Richards, Union City, Tenn.  
 694,102. Preparing alimentary extracts. Edward C. L. Kressel, London, Eng.  
 694,325. Artificial leg. John A. Peer, Philadelphia, Pa.  
 694,041. Sanitary shield for telephone transmitters. Jean B. Tauveron, New York City.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE AMERICAN YEAR-BOOK OF MEDICINE AND SURGERY. Being a Yearly Digest of Scientific Progress and Authoritative Opinion in All Branches of Medicine and Surgery, drawn from Journals, Monographs, and Text-Books of the Leading American and Foreign Authors and Investigators. Collected and arranged with Critical Editorial Comments. Under the General Editorial Charge of George M. Gould, M.D., Medicine and Surgery. Cloth, Pp. 715 and 684 respectively. Price, \$3.00. Philadelphia and London: W. B. Saunders & Co. 1902.

HANDBOOK OF BACTERIOLOGICAL DIAGNOSIS, FOR PRACTITIONERS, including Instructions for the Clinical Examination of the Blood. By W. D'Este Emery, M.D., B.Sc. Lond., Lecturer on Pathology and Bacteriology in the University of Birmingham. Cloth. Pp. 215. Price, \$1.50. Philadelphia: P. Blakiston's Son & Co. 1902.

TOXICOLOGY. The Nature, Effects and Detection of Poisons with the Diagnosis and Treatment of Poisoning. By Cassius M. Riley, M.D., Professor of Chemistry and Toxicology in Barnes Medical College, St. Louis, Mo. Cloth. Pp. 121. Price, \$1.50. St. Louis: Lewis S. Matthews & Co.

NURSING, GENERAL, MEDICAL AND SURGICAL, With Appendix on Sick-room Cookery. By Wilfred J. Hadley, M.D., F.R.C.P., F.R.C.S., Physician and Pathologist to the London Hospital. Cloth. Pp. 326. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1902.

THE ELEMENTS OF PHYSICAL CHEMISTRY. By Harry C. Jones, Associate Professor of Physical Chemistry in the Johns Hopkins University. Cloth. Pp. 565. Price, \$4.00. New York: The Macmillan Co. 1902.

ANNUAL REPORT OF THE NEW YORK STATE REFORMATORY AT ELMIRA for the Fiscal Year Ending Sept. 30, 1901. Twenty-sixth Year-book. Illustrated. Paper. Pp. 106. Elmira: Summary Press. 1901.

TRANSACTIONS OF THE LUZERNE COUNTY (PA.) MEDICAL SOCIETY, for the Year Ending Dec. 31, 1901. Vol. IX. Paper. Pp. 204. Wilkesbarre, Pa.: E. B. Yordy Co. 1902.

REPORT OF THE TRUSTEES OF THE NEWBERRY LIBRARY for the Year 1901. Paper. Pp. 26. Chicago. 1902.

SYMPHILIS: A Symposium. Cloth. Pp. 122. Price, \$1.00. New York: E. B. Treat & Co. 1902.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 27 to March 5, 1902, inclusive:

Everett A. Anderson, contract surgeon, from Devil's Lake, N. D., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

James K. Ashburn, contract surgeon, from the General Hospital, Presidio of San Francisco, Cal., to duty at Fort Grant, Ariz.

David Baker, lieutenant and asst.-surgeon, U. S. A., member of an examining board at Fort Leavenworth, Kan., vice Lieutenant Herbert M. Smith, relieved.

William B. Banister, major and surgeon, U. S. A., to duty as attending surgeon, Washington, D. C.; leave of absence for one month granted.

Walter K. Beatty, contract surgeon, from Fort Grant, Ariz., to San Francisco, Cal., for duty at the General Hospital, Presidio of San Francisco.

Henry P. Birmingham, major and surgeon, U. S. A., member of an examining board at Fort Leavenworth, Kan., vice Major Charles Richard, surgeon, relieved.

Edward C. Carter, major and surgeon, U. S. A., from duty as attending surgeon, Washington, D. C., to San Francisco, Cal., en route for assignment in the Division of the Philippines; leave of absence for one month granted, to take effect April 1, 1902, with permission to apply for an extension of one month.

R. King Cole, contract surgeon, from Dallas, Tex., to the Division of the Philippines.

Waller H. Dade, captain and asst.-surgeon, Vols., leave of absence for one month granted.

Enid B. Erick, captain and asst.-surgeon, U. S. A., to report at Washington, D. C., for examination for promotion.

James H. Hallwood, contract surgeon, from the General Hospital, Presidio of San Francisco, Cal., to duty at Fort Leavenworth, Kan.

John Van R. Hoff, lieutenant-colonel and deputy surgeon-general, member of a board at Washington, D. C., to consider the whole subject of the uniform and equipment of officers and men.

Merritte W. Ireland, captain and asst.-surgeon, U. S. A., on his arrival at San Francisco, Cal., to proceed to St. Louis, Mo., for duty as attending surgeon and examiner of recruits in that city.

Frank R. Keefer, captain, asst.-surgeon, U. S. A., to report at Washington, D. C., for examination for promotion.

Clarence J. Manly, lieutenant and asst.-surgeon, U. S. A., on his arrival at San Francisco, Cal., to proceed to Fort Caswell, N. C., for duty at that post.

James H. McCall, contract surgeon, now at Washington, D. C., to proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Frank E. McDermott, contract dental surgeon, now at Webster, Mass., to proceed to Omaha, Neb., for duty at Fort Crook, Neb.

John D. Millikin, contract dental surgeon, now at San Francisco, Cal., to report for transportation to the Division of the Philippines, where he will be assigned to duty.

Charles E. Morrow, lieutenant and asst.-surgeon, U. S. A., former orders so amended as to direct him to report in person to the commanding general, Department of California, for assignment to duty as surgeon on the transport *Hancock*.

Edward L. Munson, captain and asst.-surgeon, U. S. A., detailed a member of the board of officers to examine candidates for admission to the Medical Corps of the Army, vice Captain F. P. Reynolds, asst.-surgeon, U. S. A., relieved.

Bonaparte P. Norvell, contract surgeon, from St. Louis, Mo., to the Division of the Philippines.

Joseph R. Parke, contract surgeon, from Philadelphia, Pa., to the Division of the Philippines.

William W. Quinton, captain and asst.-surgeon, U. S. A., from Fort Ethan Allen, Vt., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Thomas U. Raymond, captain and asst.-surgeon, U. S. A., to report at Washington, D. C., for examination for promotion.

Robert L. Richards, contract surgeon, now at San Francisco, Cal., to report for transportation to Manila, P. I., and assignment in the Division of the Philippines.

Joseph J. Shafer, contract surgeon, from Washington, D. C., to the Division of the Philippines.

Erwin L. Shores, contract surgeon, on being relieved by Lieutenant C. J. Manly, asst.-surgeon, U. S. A., to proceed from Fort Caswell, N. C., to West Bridgewater, Mass., for annulment of contract.

William H. Spiller, contract surgeon, from the transport *Hancock* to New York City, for annulment of contract.

William J. S. Stewart, contract surgeon, now at San Francisco, Cal., to report in person to the Surgeon-General of the Army for instructions.

Jerome B. Thomas, captain and asst.-surgeon, Vols., having tendered his resignation, is hereby honorably discharged from the service of the United States, to take effect Feb. 27, 1902.

Walter D. Webb, lieutenant and asst.-surgeon, U. S. A., former orders directing him to proceed to Fort Totten, N. Y., so amended as to direct him to proceed to Fort Hamilton, N. Y., for duty.

Marlborough C. Wyeth, major and surgeon, U. S. A., former orders so amended as to require him to report for duty at Fort Ethan Allen, Vt.

The following named lieutenants, asst.-surgeons, U. S. A., upon the completion of the course of instruction at the Army Medical School, Washington, D. C., will proceed to San Francisco, Cal., and report, not later than April 15, 1902, to the commanding general, Department of California, for transportation to the Philippine Islands, for assignment in the Division of the Philippines: Conrad E. Koerber, Robert U. Patterson, Roderic P. O'Connor, Roger Brooke, Jr., Verge E. Sweeney, Matthew A. DeLaney, Paul S. Halloran, Robert Smart, William R. Eastman and Perry L. Boyer. The following will report in like manner, not later than April 28, 1902: Charles C. Geer, Ernest L. Ruffner, George P. Heard, Arthur M. Line, Kent Nelson, Lloyd LeRoy Krebs, William P. Woodall, Charles A. Ragan, George W. Jean, James F. Hall, Raymond F. Metcalfe, and James M. Phalen.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending March 8: P. A. Surgeon D. N. Carpenter, detached from the *Illinois*, ordered home and granted sick leave for one month.

Dr. W. E. Griffin, appointed asst.-surgeon from Feb. 20, 1902.

P. A. Surgeon H. D. Wilson, ordered to accompany a detachment of Marines, March 8, to the Asiatic Station.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended March 6, 1902:

Surgeon H. W. Sawtelle, leave of absence for seven days from Feb. 27, 1902, under paragraph 179 of the regulations.

Surgeon T. B. Perry, granted leave of absence for twenty-three days from February 28.

Asst.-Surgeon Tallafiero Clark, directed to report to chairman of board of examiners at Washington, D. C., for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon H. H. Hastings, directed to report to chairman of board of examiners at San Francisco, Cal., for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon C. H. Lavinder, directed to report to chairman of board of examiners at Washington, D. C., for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon John McMullen, directed to report to chairman of board of examiners at Washington, D. C., for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon S. B. Grubbs, directed to report to chairman of board of examiners at Washington, D. C., for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon F. J. Thornbury, relieved from duty at Port Townsend, Wash., and directed to proceed to Honolulu, H. I., and report to the medical officer in command for duty.

### BOARDS CONVENED.

Board convened to meet at Washington, D. C., March 17, 1902, for the purpose of examining assistant surgeons to determine their fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: Surgeon L. L. Williams, chairman; Surgeon R. M. Woodward; P. A. Surgeon H. D. Geddings, recorder.

Board convened to meet at San Francisco, Cal., March 24, 1902, for the purpose of examining Asst.-Surgeon H. H. Hastings, to determine his fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; P. A. Surgeon H. S. Cumming; Asst.-Surgeon C. W. Vogel, recorder.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended March 8, 1902:

#### SMALLPOX—UNITED STATES.

Arizona: Naco, Feb. 23, 12 cases.  
Arkansas: Mississippi County, Feb. 18, 100 deaths.  
California: Los Angeles, Feb. 15-22, 6 cases; San Francisco, Feb. 16-23, 18 cases.  
Colorado: Denver, Feb. 15-22, 5 cases.  
Illinois: Chicago, Feb. 22-March 1, 2 cases; Danville, Feb. 22-March 1, 8 cases; Galesburg, Feb. 15-March 1, 4 cases.  
Indiana: Evansville, Feb. 22-March 1, 8 cases; Michigan City, Feb. 17-March 3, 1 case; Indianapolis, Feb. 15-22, 7 cases; Terre Haute, Jan. 11-March 1, 12 cases.  
Iowa: Clinton, Feb. 22-March 1, 2 cases.  
Kentucky: Covington, Feb. 23-March 2, 6 cases; Lexington, Feb. 15-22, 3 cases.  
Louisiana: New Orleans, Feb. 15-March 1, 2 cases.  
Maine: Durham, Feb. 15-19, 12 cases; Freeport, Feb. 19, 1 case; Portland, Feb. 8-March 1, 9 cases; Sanford, Feb. 19, 1 case.  
Maryland: Baltimore, Feb. 22-March 1, 2 cases.  
Massachusetts: Boston, Feb. 22-March 1, 40 cases, 5 deaths; Cambridge, Feb. 22-March 1, 9 cases; Everett, Feb. 22-March 1, 1 case, 1 death; Haverhill, Feb. 23-March 1, 1 case; Holyoke, Feb. 22-March 1, 9 cases; Malden, Feb. 22-March 1, 1 case; Newburyport, Feb. 22-March 1, 1 case; North Adams, Feb. 22-March 1, 1 case; Quincy, Feb. 22-March 1, 1 death; Somerville, Feb. 15-March 1, 6 cases; Waltham, Feb. 22-March 1, 1 case; Weymouth, Feb. 15-March 1, 3 cases.  
Michigan: Detroit, Feb. 22-March 1, 2 cases; Grand Rapids, Feb. 22-March 1, 2 cases; Ludington, Feb. 22-March 1, 6 cases.  
Missouri: Hannibal, Feb. 1-28, 6 cases.  
Montana: Butte, Feb. 16-23, 6 cases.  
Nebraska: Omaha, Feb. 22-March 1, 55 cases.  
New Jersey: Camden, Feb. 22-March 1, 5 cases, 1 death; Jersey City, Feb. 23-March 2, 19 cases; Plainfield, Feb. 22-March 1, 1 case, 1 death; Newark, Feb. 22-March 1, 24 cases, 2 deaths.  
New York: Binghamton, Feb. 23-March 2, 10 cases, 1 death; New York, Feb. 22-March 1, 56 cases, 11 deaths.  
Ohio: Cincinnati, Feb. 22-28, 7 cases; Toledo, Feb. 22-March 1, 1 case.  
Pennsylvania: Allegheny, Feb. 22-March 1, 8 cases; Philadelphia, Feb. 22-March 1, 62 cases, 17 deaths; Pittsburg, Feb. 22-March 1, 6 cases; Scranton, Feb. 15-22, 1 case.  
Rhode Island: Providence, Feb. 22-March 1, 4 cases, 1 death; Warwick, Feb. 15-22, 3 cases.  
South Carolina: Charleston, Feb. 22-March 1, 2 cases; Greenville, Feb. 15-22, 3 cases.  
Tennessee: Memphis, Feb. 22-March 1, 24 cases; Nashville, Feb. 22-March 1, 1 case.  
Texas: Houston, Feb. 22-March 1, 32 cases.  
Utah: Salt Lake City, Feb. 8-22, 2 cases.  
Vermont: Burlington, Feb. 15-22, 17 cases.  
Washington: Spokane, Feb. 15-22, 26 cases; Tacoma, Feb. 16-23, 14 cases.  
Wisconsin: Fond du Lac, Feb. 22-March 1, 6 cases; Green Bay, Feb. 23-March 2, 10 cases; Milwaukee, Feb. 22-March 1, 2 cases.

#### SMALLPOX—FOREIGN.

Austria: Prague, Feb. 8-15, 10 cases.  
Colombia: Cartagena, Feb. 15, 3 deaths; Panama, Feb. 17-24, 50 cases, 10 deaths.  
France: Paris, Feb. 8-15, 3 deaths.  
Great Britain: Cardiff, Feb. 1-8, 1 case; Dublin, Feb. 8-15, 3 cases; Dundee, Feb. 8-15, 4 cases; London, Feb. 8-15, 1185 cases, 64 deaths.  
India: Bombay, Jan. 27-Feb. 4, 3 deaths; Calcutta, Jan. 11-Feb. 1, 3 deaths; Karachi, Jan. 19-Feb. 2, 34 cases, 8 deaths; Madras, Jan. 25-31, 1 death.  
Italy: Rome, Dec. 27-Jan. 4, 2 deaths.  
Mexico: Mexico, Feb. 8-16, 1 death.  
Russia: Moscow, Feb. 1-8, 20 cases, 6 deaths; Odessa, Feb. 8-15, 1 case, 3 deaths; St. Petersburg, Feb. 1-15, 14 cases, 3 deaths.  
Uruguay: Montevideo, Jan. 11-18, 65 cases, 5 deaths.

#### YELLOW FEVER.

Mexico: Vera Cruz, Feb. 15-22, 1 case, 1 death.  
West Indies: Curacao, Feb. 1-8, 1 case, 1 death.

#### CHOLERA.

India: Bombay, Jan. 27-Feb. 4, 1 death; Calcutta, Jan. 11-Feb. 1, 159 deaths; Madras, Jan. 25-31, 1 death.

#### PLAGUE—UNITED STATES.

California: San Francisco, Feb. 22, 1 case, 1 death.

#### PLAGUE—INSULAR.

Hawaii: Honolulu, Feb. 18, 3 deaths.

#### PLAGUE—FOREIGN.

China: Hongkong, Jan. 11-18, 1 death; Shantung, Jan. 18, in creasing; Young Koong, Jan. 18, 60 deaths.  
India: Bombay, Jan. 27-Feb. 4, 538 deaths; Calcutta, Jan. 11-Feb. 1, 193 deaths; Karachi, Jan. 19-Feb. 2, 107 cases, 90 deaths; Madras, Jan. 25-31, 1 death.  
Russia: Batoum, Feb. 5, 1 case.

### THE USE OF THE GALL-BLADDER TO RESTORE A PROLAPSED LIVER.\*

A. F. JONAS, M.D.

OMAHA, NEB.

Conditions concerning a descent or displacement of the abdominal organs have all too often escaped notice and are not sufficiently considered in the management and treatment of the disturbed secretory and digestive functions. That every organ should occupy its normal location to perform its proper function is self-evident; and that any deviation from the normal position is at the expense of its real office, is easily understood. Our attention to-day will be directed to one organ, the liver. That this organ is sometimes displaced downward to a considerable degree will be shown by the two following cases. That there is usually modified function and a well-defined clinical picture belonging to this change of position will also be shown.

CASE 1.—Mrs. S., aged 41, housewife, entered St. Joseph's Hospital, June, 1896. She had for three years suffered from paroxysms of severe pain located in the right hepatic region. These pains, always sudden in onset, sometimes subsided in the course of one or two hours, but occasionally continued until relieved by opiates. Whether they were relieved spontaneously or by anodynes, they were always succeeded by nausea and an aversion for food lasting from two days to a week. During the intervals, she had a dragging pain in the right hypochondriac region. A year previously she had had a moderate degree of jaundice. Otherwise her history was negative.

Status præsens: On examination, she was found apparently older than her real age, fairly well nourished. Her abdomen was distended, tympanitic, the abdominal walls were pendulous, soft and flabby, covered with numerous striae, the result of child-bearing. On palpation, pain on pressure was elicited over the region of the gall-bladder, but no enlargement of that viscus could be made out. A movable lump was found between the right costal arch and the iliac crest, which proved to be the right kidney. The diagnosis was biliary calculi in the gall-bladder and movable right kidney. Cholecystotomy and nephrorrhaphy were recommended and agreed to by the patient.

Operation: After the usual preliminary preparations, a vertical incision was made, beginning at a point over the median end of the ninth rib and extending downward four inches. On entering the abdominal cavity, the lower margin of the liver was three finger-breadths below the costal arch. The liver could very easily be elevated to its normal position, but it descended very slowly when pressure upwards was released. In appearance it was normal. The gall-bladder was easily found and several calculi could be felt through its walls. The displaced and movable kidney could be made out. The liver could be held in place by little effort, particularly when an

ordinary amount of traction was made on the gall-bladder, so the question presented itself, why not use the gall-bladder as a suspensory ligament? Accordingly, it was sutured in the uppermost part of the wound, snugly against the costal arch, the sutures passing through the gall-bladder wall, the parietal peritoneum and muscles. Before closing the peritoneal cavity, an exploration was made for the movable kidney, but it had receded to its normal position and could not be displaced. The peritoneum was then closed, the remaining wound sutured in the usual way save to allow for opening the bladder. This was done and seven calculi were removed. A long drainage tube was introduced and the wound was then dressed by an antiseptic hygroscopic pad. The drainage tube was removed in one week. The wound closed at the end of four weeks. The patient was directed to wear a snugly fitting abdominal band. Subsequently, several examinations were made. On percussion, the liver had remained in its normal position and the dragging pain had disappeared. No displacement of the kidney could be made out although she assumed several positions, straining in various ways. It was evident that the descended kidney was dependent on the descent of the liver. Unfortunately, in this case, it was not ascertained whether there was associated a downward displacement of the stomach and colon.

The foregoing experience has been the means of a more thorough examination, particularly as to the position of the liver and other abdominal viscera, in all our cases of affections involving the gall tracts. It is a fault to which we must all plead guilty more or less, that of ascribing all symptoms in a given case to the chief pathological factor and overlooking other deviations from the normal equally as important and often contributing a large share to the symptomatology. Prolapsed abdominal viscera are frequently observed and their rectification in only a few instances has been solved. Occasionally only one organ may have descended, often more than one, as in the foregoing case. Such a state of affairs is further illustrated in the following instance:

CASE 2.—M. A., aged 65, farmer, gave the following history: He had always been well, except for the diseases incident to childhood and an old right femoral hernia, until three years ago, when he had a sudden attack of severe pain in the right hypochondriac region, which was designated gall-stone colic and which subsided in an hour after the hypodermic administration of morphin. There was no jaundice with that attack. The pain has recurred at irregular intervals to the present time. It has always occurred in the same locality and often with most excruciating, being invariably associated with more or less tenderness on pressure along the border of the right costal arch. Nausea and vomiting were often present during and after an attack. During the last year, he began to experience a dragging feeling in the right hepatic region during the periods of intermission. His hernia had become irreducible and exceedingly painful, which was the cause of his seeking the hospital. He was admitted to the M. E. Hospital in January, 1901, and we found the following conditions.

\* Read before the Western Surgical and Gynecological Association, at Chicago, Dec. 18-19, 1901.

Status præsens: He was sparely built, of medium height and appeared much older than his actual age. He appeared intensely jaundiced. His pulse was 80, temperature 99. His abdomen was distended. He had a right interstitial femoral hernia. A sensitive, rounded, hen-egg sized swelling could be felt about four inches below the costal arch. On percussion, the hepatic dullness began at the lower margin of the seventh rib and extended downward fully three inches below the costal margin. On palpation, the lower margin of the liver could be plainly felt at the lower boundary of dullness. The stomach was then distended with air through a stomach tube; its lower curvature reached to the umbilicus, but it did not seem dilated. The diagnosis was irreducible interstitial femoral hernia, biliary calculi in the gall-bladder and common duct, with a prolapsed liver. An immediate operation for the hernia and subsequent surgical intervention for the cure of the biliary obstruction was readily consented to on the part of the patient.

Operation: On account of his enfeebled condition, it was considered inadvisable to do more than to immediately relieve the incarcerated hernia. The hernial tumor had increased in size until, in its upward and outward direction, it reached to the iliac spine. Toward its median direction, it extended to the pubic spine. Through a long oblique incision the hernial sac was easily enucleated and its contents were readily reduced after the hernial opening had been enlarged. The neck of the sac was transfixed with catgut and the sac was cut away. The margins of the hernial opening were approximated with silver sutures and the skin with a subcuticular silkworm gut. The healing process was uneventful. Two weeks later the second operation was undertaken.

On opening the abdomen by a vertical incision, the liver was seen to extend about three inches below the costal margin. The distended gall-bladder appeared below the hepatic border. The liver was easily pushed upward to its normal position. The right index finger was introduced into the foramen of Winslow. A calculus was found to be lodged in the common bile duct. This calculus, in its duct, was raised forward, it was easily laid bare and after the introduction of four sutures in the duct wall, the calculus was removed through a longitudinal incision. The wound was then closed by tying the previously applied sutures. The gall-bladder was then fastened in the uppermost part of the wound, snugly against the costal arch. After placing a rubber drain, with one end reaching to the common duct over the line of sutures, the other end projecting from the lower end of the abdominal wound, the peritoneum was closed, allowing the gall-bladder fundus to project at its point of attachment. The gall-bladder was opened and four calculi were removed. A rubber drain was placed in the bladder and the abdominal parietes were approximated between the two drains. The healing process was uneventful, the lower drain being removed in five days, the upper one in ten days. The liver had retained its normal location, as was indicated by the normally located area of dullness. The stomach was apparently in its normal location, as was shown by air inflation through a tube. He was discharged, wearing a snugly fitting abdominal band. The liver has remained in its normal position, as has been ascertained by a recent examination and by a disappearance of all discomfort.

As we review the foregoing cases several propositions present themselves for consideration: 1. What is the cause of hepatoptosis? 2. Does the liver descend alone or are other abdominal organs involved? 3. Is the gall-bladder, as utilized in the preceding cases, an efficient support?

In this connection we will exclude such displacements as are brought about by neoplasms or by conditions that augment the size of the organ permanently. It is intended that our discussions will be limited to displacements where the liver itself is free from histological changes and where its modified function is dependent on the descent of the organ.

Let us at the outset have a clear understanding of the normal supports of the organ. "We find that the

normal position of the liver is dependent chiefly on its intimate connection with the vena cava inferior. This great vessel, passing upward to the heart, is closely adherent to the back wall of the abdomen, is deeply lodged for some inches of its upper portion in the substance of the liver and receives from this viscus the few great and many small hepatic veins. The support afforded by the underlying hollow viscera—the stomach and bowels—is not to be ignored. Usually these are occupied to a considerable extent by gas and thus act as a sort of air cushion upon which their bulky associate can repose. The fibrous cord, which results from the atrophy of the umbilical vein of intrauterine life and is known as the round ligament of the liver, does its share in holding up the organ. Its upper part is firmly fastened in the umbilical fissure, from the front end of which it passes down, close to the anterior abdominal wall, enclosed in the free edge of the falciform ligament and terminates at the navel, with the cicatricial tissue of which its free end is fused. Finally, there are four ligaments formed by folds of peritoneum: the superior, formed by the serous tunic; the suspensory, because the liver seems to hang from it; the broad and the falciform."—Gerrish.

"The force by which the liver is retained within the arching dome of the diaphragm is a considerable one. Luschka compares the intimate contact of the two curved arches of the diaphragm and liver to a great ball and socket joint, held together by atmospheric pressure. The path that the liver must describe when it descends from its normal position is the same it took when it rose from its fetal situation. In its descent the liver goes through a peculiar axis rotation. The direction of this rotation is toward the anterior and inner portion of the abdomen. The duodenum, pylorus and hepatic flexure of the colon, will, of necessity, for anatomical reasons, have to descend with it. The posterior lower edge of the liver rises during this axial rotation and becomes superimposed on the upper end of the kidney; if there has been a predisposition to abnormal motility or loose attachment of the kidney, it will become completely dislocated."<sup>1</sup> The abdominal muscles are also important factors in maintaining the normal position of the liver as well as the other abdominal contents.

It is clear that we must consider these several factors: 1, the intimate contact of the two arched surfaces between the liver and diaphragm; 2, the suspensory ligaments; 3, the intimate relations between the vena cava inferior and the liver; 4, the hollow viscera; 5, the abdominal walls.

The suspensory ligaments of the liver are not adequate in themselves to support the organ. Nor can the hollow viscera be depended upon; nor the attraction between the well-fitting surfaces of the liver and diaphragm; nor the round ligament; nor the attachment to the vena cava; nor the abdominal walls. It is evident that each one and all of these supports are necessary. Any defect in one or more of them invites a displacement. Should, for example, the abdominal walls lose their tenacity by prolonged over-distension due to constipation, or by repeated pregnancies, the abdominal viscera must, of necessity, become displaced, gradually involving, to a greater or less degree, the entire abdominal contents, followed eventually by an elongation of the hepatic ligaments.

According to Glenard, the hepatic flexure of the colon

1. Hemmeter, *Diseases of the Stomach*, p. 705.

descends, followed by a displacement of the transverse colon, to a point where it is connected with the pyloric end of the stomach by the gastro-colic ligament; the colon becomes kinked and fecal stagnation results. When the colon has descended, the remaining viscera follow. The stomach, liver and kidneys descend in their turn. Accordingly, we have a secondary hepatic displacement, dependent primarily on a descent of the hollow viscera.

A primary displacement of the liver may be brought about, first by a trauma, forcibly displacing the organ downwards and injuring its ligamentous supports: second, by a prolonged increase in weight of the liver, due to venous or biliary obstruction.

Confining our observations to the cases herein detailed, we found several conditions common to both. The abdominal walls were relaxed. There was more or less gaseous distension. The bowels were more or less constipated. All these conditions favor enteroptosis. While in our first case we failed to establish displacements aside from the liver and kidneys simply because of lack of sufficient examination, yet gastropnoxis and enteroptosis must have been present, because it is inconceivable that a liver could be so prolapsed as that was without crowding down organs located beneath it. In our second case we established the existence of a prolapsed stomach and intestines; there existed a biliary obstruction due to a location of a calculus in the common duct, producing almost complete biliary obstruction. As a consequence the weight of the liver was increased, a condition which, no doubt, contributed to its descent.

Now the query arises, Did the biliary calculi play a rôle as an etiological factor in the prolapsus, or did they play only an incidental rôle? Did the prolapsus cause the formation of the calculi? These are questions that are not included in the scope of this paper and do not concern us at this time.

Confining ourselves to our main propositions, our last one can be briefly answered. In both our cases the liver has remained in its normal position, as has been ascertained by recent examinations. The area of liver dulness has remained normal, and the dragging sensation in the right side, complained of by both patients, has disappeared.

The use of the gall-bladder to suspend the descended liver appears practical. But to make it effective the abdominal walls should be assisted for a considerable period by an abdominal band. If the relaxed abdominal walls are not assisted to overcome the enteroptosis, the gall-bladder attachment would, no doubt, become elongated or entirely detached, favoring recurrence. In attaching the gall-bladder as we did, we simply lifted the outer edge of the liver upward and outward so as to overcome the rotation downward and inward. In conclusion we may say:

1. The cause of hepatoptosis consists in a modification of one or more of its normal supports, or in an increase in the size and weight of the liver.

2. It is impossible for the liver to descend without producing a descent of the hollow abdominal viscera.

3. The utilization of the gall-bladder as a suspensory ligament, to maintain and hold in its normal position a prolapsed liver, together with certain other abdominal organs, seems practical.

## END-TO-END APPROXIMATION OF THE BROAD LIGAMENTS AND OTHER POINTS OF TECHNIQUE IN ABDOMINAL HYSTERO-MYOMECTOMY.

E. C. DUDLEY, A.M., M.D.

CHICAGO.

Abdominal hystero-myomectomy may be, supra-vaginal, in which the tumor, corpus uteri and supra-vaginal portion of the cervix are removed, or, complete, in which the tumor and entire uterus are removed. The two operations will be considered separately.

### SUPRAVAGINAL HYSTERO-MYOMECTOMY.

The usual operation is to secure the ovarian and uterine arteries by means of strong catgut ligatures and after the removal of the tumor, corpus uteri and supra-vaginal portion of the cervix, to close the uterine stump by means of a continuous suture running from side to side and then to close the wound in the broad ligaments by means of another continuous suture also running in the same direction (Fig. 1). This method is open to the following objections: 1. The severed broad ligaments retract to the sides of the pelvis where they can no longer give adequate support to the bladder, vagina and the rectum, and where they consequently permit

Fig. 1.—Supravaginal hystero-myomectomy. The ovarian and uterine arteries have been secured by means of strong catgut ligatures; the uterine stump has been closed by a continuous suture running from side to side and the wound in the broad ligaments is being whipped together by a continuous catgut suture running in the same direction. The ligatures on the uterine arteries are covered in by peritoneum; those on the ovarian arteries are not so covered.

exaggerated descent of the pelvic floor with disabling and permanent cystocele and rectocele. 2. The rectum and bladder are brought into close relations with only a thin wall between them so that the possibility of infection from one to the other is increased. 3. In many cases the bladder is drawn over the uterine stump in order to cover it and this may give rise to mechanical irritation of the bladder. The author has attempted to overcome the difficulties above mentioned by closing the uterine stump in the antero-posterior direction and the broad ligaments in the same direction by end-to-end approximation. This method will be set forth under the following description of technique:

**Technique of Supravaginal Hystero-myomectomy.**—The steps of the operation are these:

A. Abdominal incision.

B. Delivery of the tumor through the abdominal wound.

C. Ligature of the ovarian and uterine arteries and

removal of the tumor together with the corpus and supravaginal portion of the cervix uteri.

D. Toilet of the peritoneum.

E. Closure of the abdominal wound.

A. In case of a large tumor the abdominal incision should be made nearer the umbilicus than the pubes, to

tinue, be sufficiently enlarged to permit the delivery of the tumor.

B. The delivery of the tumor through the abdominal wound is sometimes made by pressure on the abdominal walls around the incision, so as to squeeze it out as one would squeeze pus out after opening an abscess.

Fig. 2.—*Supravaginal hysteromyomectomy.* Forceps B B clamp the ovarian artery as it passes inward through the broad ligament toward the uterus. Forceps A A clamp the ligament close to the uterus and prevent reflex hemorrhage from the utero-ovarian anastomosis at the uterine end of the broad ligament. On either side the broad ligament has been divided by means of scissors between forceps A and B. The peritoneal investment of the uterus all around the cervix has been divided just above the level of the bladder attachment. The circumuterine peritoneum together with the attached bladder has been stripped down toward the vaginal portion of the cervix to the region of the uterine arteries. The uterine arteries have been clamped by means of forceps C C.

avoid the bladder, which by the growth of the tumor is not infrequently drawn up out of the pelvis. The incision, first exploratory—that is, large enough to admit one or two fingers—may, if the operation is to con-

Usually, however, the tumor is delivered by traction with the hands or with heavy vulsellum forceps. In many cases the tumor is so firmly fixed in the pelvis that it can not be brought through the abdominal wound until

after some of the ligatures have been placed around the arteries and the mass partially severed from the broad ligaments. If the abdominal incision has been very long, and the intestines are much inclined to protrude through the wound, they may, as soon as the tumor has been brought through, be held back by large flat gauze pads.

facilitated by the use of long-bladed forceps to secure temporary hemostasis of the uterine and ovarian arteries while the mass is being removed. This use of the forceps will enable the operator to get the tumor rapidly out of the way and to complete the operation with great speed and during the operation to avoid hemorrhage.

Fig. 3.—Supravaginal hysteromyomectomy. Forceps A A, B B and C C in place as shown in Fig. 2; ligatures for permanent hemostasis of the uterine and ovarian arteries in place, but not tied. Uterus being removed by scissors in such a way that the uterine stump may be sutured in a line from before backward instead of from side to side.

or by suture of the upper part of the wound. It is clearly important to prevent protrusion of the intestines and thereby to lessen exposure of the peritoneum.

C. In a majority of all cases of hysteromyomectomy, whether complete or incomplete, the operation may be

Figures 2 and 3 show the forceps in place, A A and B B securing the ovarian and C C securing the uterine arteries. The steps of this part of the operation are shown in Figs. 2 to 5 and are:

1. Clamp the arteries as shown in the diagrams: for-

ceps BB shut off the ovarian artery as it passes inward through the broad ligament toward the uterus; forceps AA prevent reflex hemorrhage from the utero-ovarian anastomosis at the uterine end of the broad ligament.

2. Divide the broad ligaments by means of scissors.

3. Divide the peritoneal investment of the uterus all around the cervix just above the bladder attachment; this is best done by lightly cutting around the uterus with a scalpel or pointed scissors.

4. Strip the circumuterine peritoneum together with the attached bladder down toward the vaginal portion of the cervix to the region of the uterine arteries. While stripping off the bladder its relations may be recognized by a sound in that viscus.

5. Clamp the uterine arteries by means of forceps or ligature them at once; in applying the ligatures, care is necessary to avoid the ureters which sometimes run very close to the uterus. Some operators take the precaution to have a catheter in each ureter as a guide during the operation.

6. Remove the tumor and all the uterus except the vaginal portion of the cervix by a wedge-shaped incision so directed that the uterine stump may be sutured in a

cervix—has been removed, then permanent ligatures on the ovarian and uterine arteries may be substituted for the forceps.

D. The toilet of the peritoneum consists of the following steps: 1, ligature of any bleeding points; 2, cauterization of the cervical canal with 95 per cent. carbolic acid; this may be applied on a probe or grooved director; sponges and instruments used in connection with the cervical canal should for reasons of asepsis not be used elsewhere; 3, closure of the cervical canal by suture and covering of all exposed surfaces with peritoneum (the author's method of uniting the cervical stump by a line of union in the antero-posterior direction and of bringing together the broad ligaments by end-to-end approximation is set forth in Figures 3 to 8; 4, drainage if required.

In supravaginal hysteromyomectomy drainage is usually not required; i. e., if drainage is indicated it would generally be wise to remove the entire uterus, but if drainage is required it is best made with a continuous strip of gauze passed from above downward through a free opening posterior to the cervix into the vagina; this opening should be enlarged by splitting the posterior wall of the cervix, and if necessary also the anterior wall. A gauze drain should usually be removed through the vagina about two days after the operation and the

Fig. 4.—Supravaginal hysteromyomectomy. Ovarian arteries o a, o a, and uterine arteries u a, u a, secured by the ligatures which were shown in place, but not tied in Fig. 3. One free end of each of these ligatures is cut short and the others are held in pressure forceps. Uterine stump closed by continuous suture in antero-posterior direction.

line from before backward, not from side to side (Fig. 3).

7. Place permanent ligatures on the ovarian and uterine arteries and remove the pressure forceps. It is important that the forceps be loosened by an assistant while the ligatures are being drawn tight, because if tied before the forceps are removed dangerous hemorrhage may result. The uterine arteries are located sometimes by sight, sometimes by touch and are accordingly secured by ligature, isolated or *en masse*. In some cases the tumor so fills the pelvis that the forceps for want of room can not be applied. Then, a rubber ligature having been thrown around the cervix for temporary hemostasis, the tumor may be enucleated and the size of the mass so reduced that the forceps may be applied. As the incision is carried down through the broad ligament on each side, additional forceps, if needed to control hemorrhage, may be used until the entire mass—tumor, corpus uteri, and supravaginal portion of the

Fig. 6.—Supravaginal hysteromyomectomy. o a, o a, ovarian arteries; u a, u a, uterine arteries; the cut ends of the two broad ligaments are brought together—end-to-end approximation—by tying the catgut ligatures which are shown in the grasp of pressure forceps, Fig. 4. The tying of these ligatures brings the broad ligaments into position for final end-to-end union by a continuous suture. The needle here shows the beginning of this suture.

removal of it followed by gentle douches of 0.5 per cent. lysol in sterile water.

E. The abdominal wound should be closed in the usual manner without drain.

#### COMPLETE ABDOMINAL HYSTERO-MYOMECTOMY.

The removal of the entire myomatous uterus is indicated; first, when the cervix uteri is septic or otherwise so diseased as to render the presence of any part of it unsafe; second, when on account of extensive traumatism or suppuration vaginal drainage is required. In addition to the above indications there is a certain legitimate latitude of choice so that the bias of the operator may be in the direction of complete hysterectomy.

The abdominal incision, the delivery of tumor, the clamping and ligature of the arteries, the division of the broad ligaments and the closure of the wounds, both pelvic and abdominal, are substantially the same as al-

ready described for supravaginal hysteromyomectomy. The following description of complete hysterectomy contains, however, certain peculiarities in technique:

**Excision of the Uterus.**—When the cervix is accessible through the vagina the first incisions may be made as for vaginal hysterectomy, the bladder and the rectum being stripped away from the cervix, sometimes as far as the peritoneal cavity. The broad ligaments may be separated through the vagina and tied off as high as practicable. In some cases the uterine arteries may be reached and ligatured. The vagina having been temporarily packed with a continuous strip of gauze, the final removal of the uterus through the abdomen will be found easy in consequence of the vaginal detachment. The removal of the uterus is performed as already de-

be easy. If the incisions have not extended so far, the removal will not be difficult; but if no vaginal incisions have been made, the operator may in some cases find it quite tedious, if not difficult, to work his way down into the vagina. The attempt has occasionally resulted in opening the rectum, bladder, or ureter. This difficulty may largely be overcome by a simple device as follows:

The bladder having been stripped off the cervix as far down as possible toward the vagina, the uterus is drawn by means of vulsellum forceps well up through the abdominal wound. This traction exposes the anterior wall of the cervix, which is now freely divided with sharp scissors by a longitudinal incision and the cervical canal thereby laid open (Fig. 9). One blade of the scissors is now passed directly down through the external os to

Fig. 5.—Supravaginal hysteromyomectomy. A ligature *en masse* surrounding an artery in the broad ligament is being drawn tight and tied; while the operator is tightening the ligature, the assistant is removing the forceps. If the ligature is drawn tight before the forceps are removed the artery will not be sufficiently compressed and hemorrhage may result.

scribed for supravaginal hysterectomy; the uterine arteries are usually clamped and tied a little further from the uterus. This necessitates the greatest care not to include the ureters, which cross the arteries near the uterus. The broad ligaments and circumuterine structures are then divided by means of strong scissors, as shown in the illustrations; in making the incisions for this purpose close to the uterus, no harm is done if, on either side, a small portion of the lateral walls of the cervix be left behind. The bladder is stripped away from the cervix as far toward the vagina as practicable and the peritoneum of the posterior wall of the uterus is stripped or dissected off in the same way.

If the vaginal incisions have previously extended into the pelvic cavity, the final removal of the uterus will

the vagina, and the entire anterior cervical wall is thus divided in a longitudinal direction. The finger now readily passes to the vagina, and serves as a guide for the rapid removal of the uterus by a circular incision around the cervix at the utero-vaginal attachment. In some cases it is convenient to reserve the ligaturing of the uterine arteries to this part of the operation. Small bleeding vessels are tied or twisted. If drainage is not required the wound should be closed complete both on the vaginal and the peritoneal side. This may be done by lines of union from side to side as shown in Figs. 10 and 11.

Fig. 12 shows the wound closed by end-to-end approximation of the broad ligaments. If this method is employed the same sutures that unite that part of the

broad ligaments nearest to the vaginal wound should also catch up the upper cut end of the vagina so as to draw it into the space from which the cervix has been excised and unite it to the broad ligament stumps at the point where the ligatures surround the uterine arteries; this serves to draw the vagina strongly upward and to cover the exposed surfaces between the vagina and broad ligaments.

Fig. 7.—Supravaginal hysteromyomectomy. o a, o a, Ovarian arteries; u a, u a, uterine arteries; the continuous suture for end-to-end approximation of the broad ligaments nearly complete.

Upon completion of the operation the vagina should be packed with gauze from the vaginal wound to the vulva, and a large gauze dressing placed over the vulva to absorb the drainage fluid and held there by a T-bandage, which should be changed often to keep it dry; the vaginal gauze is removed in about three days and vaginal douches of 0.5 per cent. lysol are then given twice a day.

If drainage of the pelvic cavity is required, it should be vaginal, and the vaginal wound should be left

Fig. 8.—Supravaginal hysteromyomectomy. o a, o a, Ovarian arteries; u a, u a, uterine arteries. In the case represented by this figure the broad ligaments are too short for complete end-to-end approximation. The end-to-end approximation is therefore carried only part way, but the ligament and the remainder of the closure is accomplished by a line of union running from side to side. The running suture is nearly complete.

open or partly open for that purpose. The drain is introduced as follows: the end of a long strip of gauze, double thick and two inches wide, is passed from the pelvis through the vaginal wound to the vulva; the gauze is then lightly packed from below upward so as to fill

the vagina and the vaginal wound, and to cover all surfaces in the pelvis left exposed by the operation. The dressing over the vulva which receives the capillary drainage from the gauze should be kept dry by frequent changing. The gauze drain, being a continuous strip, may easily be removed by the vagina in two or three days.

In hysteromyomectomy the ovaries, if normal or

Fig. 10.—Complete abdominal hysteromyomectomy; entire uterus and tumor removed; long ends of catgut ligatures on ovarian and uterine arteries have been drawn down through the vagina to the vulva by a pressure forceps passed from the vagina through the vaginal wound, and then withdrawn with the ligatures in its grasp.

nearly normal, should be preserved. Catgut ligatures and sutures are used throughout. The ligatured part should receive nutrition by collateral circulation and all ligatures should be so introduced as not to deprive the ligatured tissues of circulation and nutrition. The proper method of applying the ligatures to the ovarian arteries as they pass through the broad ligament and to the uterine arteries as they reach the sides of the uterus is shown in the accompanying illustration.

Fig. 11.—Complete abdominal hysteromyomectomy. While the ligatured masses which contain the ovarian and uterine arteries are being held down into the vaginal wound by pressure forceps in the hands of an assistant, the operator is uniting by a continuous suture the peritoneal margins of the vaginal wound in such a way as to make the entire traumatism extraperitoneal. This suture may include and fix the ligatured masses and hold them below the line of union: it should also catch up and hold the upper cut end of the vagina in contact with the lower edge of the broad ligament.

*Advantages of End-to-End Approximation of the Broad Ligaments in Hysteromyomectomy.*—1. The broad ligaments, when approximated by this method, take the place, in an anatomical sense, of the ex-

cised uterus and form a pouch posteriorly that corresponds to the cul-de-sac of Douglas and anteriorly a depression that answers for the utero-vesical pouch.

2. The broad ligaments, if brought together end to

3. The broad ligaments when brought together by end-to-end approximation, are interposed between the bladder and rectum and thus prevent the intimate union of these two viscera—a union that would leave a very

Fig. 3.—Complete abdominal hysteromyomectomy. The broad ligaments have been divided on either side of the uterus to the region of the uterine arteries; the circumuterine peritoneum has been divided by a circular incision around the cervix and together with the attached bladder stripped down toward the vaginal portion of the cervix. All clamps which were used to secure the uterine and ovarian arteries except those next to the uterus, A A, have been removed and permanent ligatures have been placed upon the ovarian and uterine arteries, o a, o a, and u a, u a. The anterior wall of the cervix is being split longitudinally by cutting through it with scissors from the pelvic cavity to the vagina. This is to facilitate the excision of the uterus as described in the text. The long ends of the ligatures on the ovarian and uterine arteries are held out of the way by means of forceps B B.

end, give support to the rectum, vagina, bladder and other parts of the pelvic floor and in so doing prevent the descent of those parts—a descent which so commonly results from hysterectomies as ordinarily performed.

thin wall between them through which infection might pass from one to the other.

4. The operation is more quickly and easily performed by this method than by that of side-to-side union of the ligaments.

I have united the ligaments by end-to-end approximation often enough to be convinced of the feasibility and utility of the operation.

Fig. 12.—*Complete abdominal hystero-myomectomy.* The broad ligaments are brought together from side to side and united by end-to-end approximation. The upper extremity of the vagina is also closed by suture introduced from side to side so as to fasten it to the lower part of the broad ligament wound at the point where the ligatured, uterine arteries are approximated.

## ANEMIAS SECONDARY TO GASTRO-INTESTINAL DISEASE, WITH REPORT OF TWO CASES.\*

G. W. McCASKEY, A.M., M.D.

Professor of Clinical Medicine and Nervous Diseases, Fort Wayne College of Medicine.  
FORT WAYNE, IND.

The complex relationship and function of the blood stamps it as a tissue unique in the animal economy. As the common carrier of the body, it is compelled to transport every molecule which passes to and from the tissues, into and out of the organism. It is thus subjected to widely varying influences of both a physiologic and pathologic character to an extent equaled by no other tissue in the body. It is able to maintain the integrity of its function and a distinct autonomy by what may not inaptly be termed its own inherent elasticity of structure. Its cellular elements may be reduced in number under pathologic conditions to 25 per cent. or less of its physiologic standard, and yet perfect recovery be possible. Their most important chemical constituent—hemoglobin—may be reduced in each individual cell to a similar degree, with the same possibilities of restoration to a condition of perfect health.

Among the most important factors influencing the function and structure of the blood may be mentioned the digestive organs with their widely varying conditions of health and disease. The integrity of the blood, as of every other organ of the body, is, of course, obviously dependent upon the function of the digestive organs. The theory that numerous blood diseases, and especially the anemias, are frequently the direct or indirect result of morbid conditions of these organs has been formulated many times in diverse forms, and substantiated by a large amount of clinical evidence. Facts of an experimental character, bearing upon these questions, are exceedingly difficult to procure for many reasons, a few of which I will endeavor to point out. In the first place everything indicates the search for a specific organism, the metabolic products of which would

produce anemia with the same constancy that the organisms of diphtheria, syphilis, etc., produce their characteristic results, will be quite as futile in the future as it has been in the past. The conclusion seems at present justifiable that such hemolytic effects as may result from bacterial processes are to a large extent the common result of varied and indifferent toxins, using this term in its broadest sense, although some may, of course, be more active in this direction than others. The results will further depend upon the vulnerability of the blood itself as well as the blood-making organs, to the morbid influences of varied character under discussion. This vulnerability will not only vary widely in different individuals, but in the same individual at different times. In this respect it constitutes no exceptional phenomenon in pathology. That the etiologic factors of disease may be active or otherwise, according to that unknown and undefinable factor which we are pleased to term the resistive power of the organism, is a fact so well known as to scarcely need mention. Thus it happens under many conditions that a cause which has been existent for years will suddenly, owing to some change in environment or internal conditions, produce results of a most striking character. That such phenomena occur in the blood is a fact which has been abundantly illustrated in my own clinical observation, and is in fact shown by the cases which will be later reported. With regard more especially to the action on the blood of poisons formed in the gastro-intestinal canal, there are many conditions by which they may be modified aside from the vulnerability of the blood itself. The epithelium of the intestinal canal, and the entire structure of the liver, stand as important intermediate laboratories between the gastro-intestinal contents and the blood. The ordinary peptones of digestion, for instance, are toxic if introduced into the blood, but are so modified by the epithelial structures above referred to, and by the liver, as to lose their toxic properties and be assimilable by the organism. The observations of Kottwitz<sup>1</sup> on gastro-intestinal mucosa in cases of leukemia sustain this proposition.

So far as the direct actions of poisons on the blood are concerned, clinical observations of an explicit and demonstrable character are not entirely lacking. Ehrlich, for instance, says explicitly that the resistance of the blood cells as tested by the action of dilute salt solution and electric discharges from Leyden jars, etc., is increased after many intoxications. The degree of virulence which will be manifested by gastro-intestinal toxins when they find their way into the circulating fluid will be obviously dependent, 1, upon the degree of virulence of the micro-organism itself which for the same species varies greatly at different times, and 2, upon the integrity and functional activity of the defensive mechanism above referred to which nature has placed as a barrier for the protection of the blood and, of course, all the organs which it supplies. It may thus happen that the colon bacillus, which is constantly present in health in the large intestine, may under modified conditions become exceedingly virulent and its action upon the blood and other tissues suddenly become of a severely toxic character. Such a change has, in fact, been experimentally demonstrated to take place with this particular organism. Finally, I wish to call attention to a fact that I do not remember seeing emphasized, viz., that some agents, such as potassium chlorate, which produces a leucocytosis, also produces destructive changes upon the erythrocytes in the circulating fluid.

\* Presented to the Mississippi Valley Medical Association, at Put-in-Bay, Lake Erie, Sept. 13, 1901.

1. Ewing: Pathology of the Blood, 1901, p. 201.

I have found moderate leucocytosis in a large proportion of the cases of intestinal toxemia wherever the reaction to the organism was sufficiently strong to produce it, and I believe that there is good reason for assuming a hemolytic action upon the erythrocytes under many, if not most of the conditions which produce a leucocytosis. Of course this does not exclude the possible hemolytic action of certain toxins such as those of tuberculosis, which do not produce a leucocytosis.<sup>2</sup>

In this connection, the recent experimental and clinical observations of White and Pepper<sup>3</sup> on the granular degeneration of the erythrocytes produced by lead are exceedingly suggestive as to possibilities of chemical poisons acting on the erythrocytes. I have frequently observed the granular changes which they describe, but have regarded them as artefacts, due possibly to errors in technique, although that technique was apparently uniform. It seems reasonably certain that there are other structural changes in the erythrocytes which are not demonstrable by present methods of research, produced by a variety of chemical agents circulating in the blood. The resistive power of the red cell to different dilutions of normal saline solutions, as well as its varied resistance to other destructive agents—such as a shock from a Leyden jar, etc.—can only be due to variations in the construction of the cell, the nature of which can not at present be determined. The recent studies of Ehrlich and Morgenroth, an excellent summary of which has recently appeared in Meltzer's<sup>4</sup> article, also point to the same conclusion. The hemolytic actions of certain alien serums is a remarkable phenomenon, and points to the probability of there being many chemical agents which may find their way into the blood, as factors in lowering the resistive power of the red cells, and leading to premature senescence and decay.

The following cases are briefly outlined as furnishing clinical evidence in supporting the views already set forth:

CASE 1.—I. D. M., a patient of Dr. Wright of Convoy, Ohio, consulted me June 11, 1901, complaining of extreme weakness, loss of appetite, pain in the back, palpitation of the heart, dyspepsia, and disturbance of the stomach function.

The stomach symptoms were of long duration, his health having been somewhat impaired in this respect for a number of years. Three months before my examination he began to run down in strength until within a few weeks the exhaustion had become extreme. It was progressive up to the time of his visit to my office.

The blood examination showed 1,500,000 red cells, 4300 white, 30 per cent. of hemoglobin.

Examination of the urine gave the following result: Total quantity per 24 hours, 950 c.c.; specific gravity, 1022; total solids, 25.63; urea, 2 per cent. or 19 grams. Indican and skatol were both present in moderate amounts; no albumin or sugar.

Stomach examination, Ewald test breakfast, removed in one hour, gave the following results:

Total quantity, 20 c.c.; no free HCl; total acidity, 85. Lactic acid was present in considerable quantities. Starch digestion was good; biuret reaction faint. The fasting stomach contained large quantities of cellular debris. There was also severe colitis, evidently chronic in character.

Physical examination revealed a somewhat large and indurated liver; heart normal in size, but with a mitral systolic bruit.

Examination of the dried and stained blood films showed the red cells to be of normal size with very few normoblasts and no megaloblasts. There was a very severe poikilocytosis, the

cells assuming different sizes and shapes. Measurement of less than 100 cells gave less than the normal average, about 6.5 microns.

The case was regarded as one of secondary anemia, probably resulting from disease of the digestive tract, and treatment instituted accordingly. He was placed upon Fowler's solution, with bitter tonics, and a 5-grain dose of double citrate of iron and quinin three times a day. This was not materially different from previous treatment. In addition he was given local stomach treatment every day, consisting of lavage, pneumatic gymnastics according to the method of Turek, and electricity. He was also given colon lavage for the colitis, with general hydrotherapeutic measures, particularly in the form of hot and cold douches.

Improvement was manifested in a week, and the red cell count and the hemoglobin showed progressive improvement from this time on until August 7, less than two months from my first examination, when the red cells numbered 5,000,000 and the hemoglobin 100 per cent. The patient's general condition was also very good, and he was discharged cured, with the exception of the gastritis, which was greatly improved, but not well.

CASE 2.—A. B. M., referred by Dr. S. E. Mentzer, Monroeville, Ind. Farmer, aged 31, complains of stomach and bowel trouble of about 5 years' duration. Health always good until that time. He once had an attack of bloody flux, and since then has had occasional bloody stools. After a couple of years he began to have stomach symptoms, and for the last two years his health has been in bad condition. Shortly after eating he has abdominal distress, followed by thin, watery movements mixed with particles of unchanged food. He has lost 40 pounds in weight. His limbs were covered with purpuric spots in varying grades of intensity, some deep purple and others much faded, from the size of a silver dollar up to the size of one's hand. For two weeks before examination he has had extreme dyspnea on slight exertion.

Physical examination shows enlarged spleen, liver and heart with systolic bruit, most marked over the apex. Blood examination showed 1,700,000 red cells, hemoglobin about 25 per cent. Examination of the urine; total quantity, 250 c.c.; specific gravity, 1030; total solids, 24.36; urea, 4 per cent. or 14 grams; skatol and phenol in abundance, but no indican and no albumin or sugar.

A somewhat similar line of treatment, modified with special reference to the altered pathological conditions of the intestines, was instituted. The patient was unable to leave his room in the hospital, the exhaustion was so extreme.

Improvement was very slow in appearance in this case, although an increase in the red blood cells and hemoglobin was manifested after a week or ten days. After this time improvement was progressive, and in three and one-half months from the time of treatment he was discharged with the anemia cured, the red cell count having reached 5,000,000 and the hemoglobin 100 per cent. The chronic gastro-intestinal disease was much improved, and the general physical condition very satisfactory, the patient being able to do light work on his farm. He is still continuing treatment for the gastro-enteritis under the care of his family physician.

So far as one can judge the histo-chemical pathology of the blood, these cases were certainly secondary anemias, and whatever view may be taken of the precise pathological processes involved, the previous history of the cases, and the therapeutic test appear to establish the etiologic roll of the gastro-intestinal disease. This is the practical clinical fact, and, in attempting its explanation we may freely admit the debatable character

2. Clinically, leucocytosis is commonly found in phthisis, but it is due to a mixed infection.

3. American Jour. Med. Sciences, September, 1901.

4. New York Medical Record, Aug. 3, 1901.

of the ground upon which we stand. Indeed, it seems to me that to insist upon any single factor as playing an exclusive rôle is to take too narrow a view of the situation. We should, for instance, recognize, 1, the importance of the varying grades of subnutrition encountered; 2, the chemical factor, the precise nature of which can not usually be determined, but the existence of which, as a factor in morbid hemogenesis, is substantiated by a mass of clinical and experimental evidence, quite conclusive in character, and includes, in its broader relations, not only the products of digestion unmodified by the physiologic functions of entero-hepatic structures and bacterial ptomains, but the leucomains of normal or morbid metabolism, and the products of bacterial growth on all mucous surfaces or parenchymatous structures; and last, but perhaps not least, because of its greater permanence, that intangible something, the expression of a hereditary or acquired vice, which determines what has been called the vulnerability of the tissue or organ. Such, it appears to me, is the broad view which clinical medicine should take of these cases, and in calling attention to the rôle of gastro-enteric disease, with a report of a couple of selected cases, I would especially emphasize the importance of not losing sight of the other factors to which attention has been called.

### THE ANATOMIC FACTOR IN THE PRODUCTION OF BALDNESS.

GEORGE ELLIOTT, M.D.

ASSISTANT DEMONSTRATOR OF ANATOMY, TRINITY MEDICAL COLLEGE, TORONTO.

Cunningham, in opening his chapter on the dissection of the scalp, says: "Strictly speaking, the term 'scalp' should be restricted to the soft parts which cover the vault of the cranium above the level of the temporal ridges and the superior curved line of the occipital bone"; whilst Treves states it is convenient to consider the term "scalp" as limited to the structures formed by the union of the first three layers, viz., the skin, the subcutaneous fatty tissue or superficial fascia, and the occipito-frontalis muscle and its epicranial aponeurosis.

How strikingly does the scalp area of Cunningham correspond with the area of baldness as seen in most individuals the subjects of this condition! But still more precisely and accurately does the area of baldness correspond to the area of the epicranial aponeurosis, a structure in which there are no muscular fibers nor yet any underlying muscular fibers between it and the bone. That the production of baldness has an anatomic factor, I propose now to discuss more in detail.

The skin of the scalp is intimately connected with the underlying epicranial aponeurosis by the superficial fascia. In fact these two structures are so firmly attached by dense fibrous bands that it is a difficult undertaking for a dissector to essay their separation. Among these meshes lie the fatty tissue, the nerves and the vascular structures before they break up to supply the skin. Similar superficial fascia is found in the palms of the hands and the soles of the feet; and it may be significant to note that of the three regions of the body supplied with this dense superficial fascia, the overlying skin in the two latter is altogether destitute of hairs, whilst the third, the scalp area, very often becomes similarly destitute in later life.

Any one who takes the trouble to examine and observe closely must be struck by the fact that baldness occurs on the top of the head and rarely if ever extends

below the temporal ridges latterly, or even down to the superior curved lines of the occipital bone posteriorly. It will be noticed also that baldness extends lower in the middle line behind than it does an inch or so on either side of the middle line posteriorly. This, of course, corresponds to the fact that there are no muscular fibers in the middle of the occipito-frontalis muscle at its attachment to, or rather origin from, the external occipital protuberance and the adjacent parts of the superior curved lines.

The skin of the scalp, therefore, overlying the epicranial aponeurosis, has no underlying muscles to exercise it, and has only to depend upon the action of the occipito-frontalis muscle to which it is closely adherent, and only moves when that muscle is put into action; and how often that muscle is moved in twenty-four hours, I leave any one to conjecture. In no other region of the body is there such an extensive area of skin which does not receive adequate exercise either through underlying or adjacent muscles.

The skin of the area of baldness is abundantly supplied with blood; the scalp is very vascular. There is nothing anatomic or mechanical to interfere with or retard the arterial supply, unless it be the proverbial constriction of the hat assumed by the male portion of the population. As far as this acts upon the arterial trunks, it is infinitesimal, but upon the return flow in the lymphatics and veins the hat has its influence.

The lymphatics and veins drain the area of baldness in five different directions. On either side of the middle line anteriorly, there is a lymphatic stream down the forehead past the nose and over the face to the submaxillary glands. Latterly these vessels lead to the lymphatic parotid glands; posteriorly, into the post-auricular and suboccipital glands. The fifth is along the path of the emissary veins through the parietal foramina when present in the parietal bones, into the superior longitudinal sinus. I have recently taken the trouble to examine a number of parietal bones. In a great many of these the parietal foramen, which when present is generally situated about an inch or so anterior to the posterior superior angle on either side of the sagittal suture, was absent altogether; and it was in the smaller and thinner bones that it was present. It would be, perhaps, an interesting point to know whether this parietal foramen with its emissary vein, were more constant in women than in men, as its presence must add materially to the draining facilities of this region.

Whilst the skin of this area of baldness and consequently the hair follicles may have a good nourishing supply directed towards them, the functions of the hair papillæ may be stunted by the slow return flow through the veins and lymphatics. What is there to accelerate that flow? Nothing but the inactivity of the epicranial aponeurosis, and, perhaps, to a slight extent, gravity. There is no active muscular exercise in the part whatever, to hurry along the waste products and the deoxygenized blood in the vessels. These structures being superficial and more compressible than the arteries, their compression by the rim of the hat will further retard their flow. In their passage outwards from the center of the dome, the rate of flow is dependent entirely on the gradual fall, that is, to gravity. When they approach the borders of the dome, however, the fall is precipitate. Here, also, the influence of underlying muscular structures comes into play. One can easily demonstrate this by placing the hand on the back of the head and noting the extent of skin exercised in the nodding

and turning movements of the neck. So on the sides. The temporal regions have their skin abundantly exercised through the action of the temporal muscles. Very often a tuft of hair remains for a long time over the forehead when the falling-out process is advanced to a great degree behind it. That may be due to the part being well drained on the border of the dome, which is also to some extent exercised by the anterior muscular fibers of the occipito-frontalis muscle, which fibers extend well up to the hair line in front.

Baldness does not prevail in the female sex to anything like the extent it does in the male. Very few women become bald even in far-advanced life. This is generally put down to the fact that they give more attention to their hair, dressing and combing it night and morning; and their light headgear. The scalp in them is well exercised by the combing, plaiting and throwing from side to side, movements which impart a good deal of exercise to the scalp. Women suffer from dandruff equally with men. If dandruff be the prime cause of baldness in men, why are its destructive effects not equally seen in women? Men comb and brush their hair in a minute, probably once, or twice or thrice daily. There is no exercise to the scalp in these maneuvers of a minute's duration. During the hours of sleep the dorsal or either lateral decubitus is assumed. This may have a slight effect in hastening onward the return flow from the roots of the hairs in the bald area. In the expressions of surprise, etc., when the anterior fibers of the occipito-frontalis produces wrinkling of the skin of the forehead, the exercise to the skin is beneficial to the hair over the forehead. But how often are these expressions depicted on the human countenance?—especially as age advances, and more control is exercised over the muscles of expression. If there be no anatomic factor in the production of baldness, how is it that dermatologists order massage in the treatment of calvities and the falling-out process? How is it that when the scalp has become bound down and absorption of the fat in the superficial fascia has taken place that no measure of relief can avail? Simply because the hide-bound skin can not be exercised. In scleroderma, even, the hair frequently falls out in the part affected. Massage is the substitution for exercise, and its object is to get rid of the choking and damming back in the veins and lymphatics.

The foregoing being correct, the way to treatment is pointed out. Prevention through massage-exercise is nine points in the law of treatment. This should be begun in early life, at the time when the youth is gradually developing into the more sober man, when his occipito-frontalis muscle has become more and more subordinated to his will. Massage should be performed the same way as in other regions, first freeing the vessels farthest from the seat of trouble and gradually approaching the center. It should be done at night as well as in the morning, particularly at night, as gravity has little or comparatively little chance through the day. If the scalps of men received as much exercise as the scalps of women, there should be on the vaults of their craniums a luxuriant growth of hair. The American Indian is said by Holder never to grow bald. The reason lies in their comparatively long hair. The close-cropped Indian of the Reserve is not wholly exempt.

129 John Street.

## OCULAR LESIONS ASSOCIATED WITH CONSTITUTIONAL DIATHESIS.

H. ISAAC JONES, M.D., L.R.C.P.E.  
SAN FRANCISCO, CAL.

In calling your attention to this subject the writer does not desire to create the impression that he has anything purely original to offer, but to call your attention to the fact that the human body is too much of an entity for any one system to be exclusively deranged, while others remain healthy; actions and reactions are the two great rules of organic life. Functional waves of reflex influences are always sweeping to and fro through the body and peripheral irritations of every kind, and every phase of organic disturbances may excite a reflex that will influence the actions and perhaps the nutrition of the eye and its appendages.

Sir Thomas Watson said: "We find in the eye more satisfactory and plain illustrations of the general facts and doctrines of pathology than in any other single organ of the body; certain changes in the eye are known to accompany certain diseases of the brain and spinal cord, and also certain lesions of organs more remote, which are also the expression of general and constitutional disease."

In reflex neurosis it is very difficult to tell from what part of the organism proceeds the hidden mischief, so that unless an oculist is well versed in every branch of medicine, his field of investigations will be limited. The association of ocular lesion with constitutional diseases is determined by anatomical connections, partly by histological peculiarities of the texture severally involved, but chiefly by their embryological origin and relationship. As you are aware, nearly all the tissues of the body are represented in the eye and its appendages, and are liable to all the pathological changes which affect like tissues in the body; therefore our thoughts should not be centralized on the eye itself to the exclusion of other consideration, for the ocular notation may be only a sign and symptom of the changes that are produced in the animal economy. For instance, the eye lesion in diabetes and Bright's disease is more diagnostic than prognostic.

Twedy, in his paper on "Constitutional Diseases of the Eye in the Light of Embryology," points out many highly suggestive and interesting facts in this connection. The embryological origin of the various structures of the eye from the layers of the blastoderm is represented schematically. He thus shows that there is a histological and physiological relationship between the epiblastic elements of the eye and the epiblastic tissues of the rest of the body, and between the mesoblastic tissues of the eye and all other mesoblastic tissues. He further states: "The pathological relationship is none the less intimate and exact. The cutaneous eruptions of strumous children; the eczemas, herpes, impetigos, etc., are concomitants of the phlyctenulae of the epithelial layers of the cornea. In ophthalmic herpes the corneal change is likewise epiblastic. Syphilis, on the other hand, is a disease of mesoblastic texture, and ocular syphilitic affections are found to be of the mesoblastic origin. The notched, pegged and stunted teeth of inherited syphilis are not faults of the epiblastic enamel, but of the mesoblastic dental papillae. Though epiblastic portions of the eye may become secondarily involved, the lesion begins in the mesoblastic structures. These and other analogies are valuable not only for diagnostic purposes, but also for therapeutic uses. Certain drugs have a special

affinity for particular tissue-element, and this fact may be utilized in prescriptions."

I had the honor of reading a paper before this section in 1894, on the associations of optic atrophy with locomotor ataxia. That a certain portion of the spinal cord exercises a direct influence on the eye has been beyond a doubt established by experiments of modern physiologists. We see in asthenopia, due to vasomotor paresis affecting the retinal vessels, this condition is reflex and mostly dependent upon disorders of the pelvic or genital organs. The aching sensations are apt to be more constant and less relieved by rest than in pain from errors of refraction. The ophthalmoscope will disclose a turgid condition of the retinal vessels. The third root of the lenticular ganglion is a slender filament derived from the cavernous plexus of the sympathetic, and one of the branches of the ganglion is a small filament which penetrates the optic nerve along with the arteria centralis retinae, to supply the walls of the retinal vessels. The path, therefore, from the pelvic plexus of the sympathetic is an almost straight road, and disturbance in the circulations of the pelvic organs produces a wave of vessel dilations which travel over this path. Such cases can not look fixedly for any length of time at any object, near or remote, without exciting severe pain in or about the eye.

Again, in disease of the eye in connection with pregnancy, it can not be a matter of surprise that in some instances the effect of this general disturbance should be felt in the organ of sense, and therefore in the eyes, which respond so readily to any disorder of the vascular or of the nervous system. Unless the symptoms are very prominent they are not complained of by the patients. If they do, it is put down by the family physician to general indisposition or disorder of the digestive organs, and especially the liver.

Hysterical patients, in their psychological condition, may present almost any symptom of disease without the existence of any lesion to which such symptom could be referred. We see spasmodic action of the external muscles of the eyeball in neurotic subjects. Young ophthalmic surgeons perform tenotomy as a cure for all the ills that nerves are heir to; in fact, the external muscles of these hysterical patients are, in a large proportion, not better balanced than their minds.

*Lithemia.*—Lithemia is another cause of eye trouble. You all have seen Hutchinson's "hot eye." Mr. Hutchinson has illustrated in his works the connections of certain diseases of the eye with gout, also gout with destructive form of iritis. Intermission is characteristic of ocular gout. Of the poisonous waste products, those of the uric acid type are the most prolific in producing constitutional disturbances, acting directly as irritants and indirectly on the nervous system, causing tenderness and pain of the ciliary regions, troubles of accommodations which no glass will correct, and often called spasms of the accommodations, and floating spots in the vitreous. These symptoms disappear when attention is paid to the systemic trouble, administration of salicylates and lithia salts.

*Gastric.*—To the stomach and the alimentary canal is due the origin of the phlyctenular ophthalmia of children caused by ptomaines from the mal-digested articles of food and from their absorption into the system, producing other eye troubles of an intermittent character.

*Teeth.*—The mutual relationship between the teeth and the eyes are more intimate than is commonly supposed, no doubt due to the anatomical connection

through the ganglionic filament of the first branch of the fifth nerve to the lenticular ganglion, which is in connection with the third nerve by its short root. We often see conjunctivitis, neuralgia and lachrymation due to some pathological trouble in the teeth, the reflex trouble disappearing as soon as the dental trouble is corrected.

*Ear.*—How often we find ophthalmic patients to be at the same time laboring under some affection of the ears. For example, in children with serofulous ophthalmia, there is often chronic inflammation of the drumhead, with discharge from the ears; example of connections of disease of the ears with disease of the eye is the super-vention in cases of keratitis or kerato-iritis from congenital syphilitic taint. Numerous ocular manifestations of influenza or la grippe are reported by various observers.

*Nose.*—The lachrymal passages which maintain a communication between the conjunctival space and the nasal cavity are the seat of some of the most troublesome affections of the eyes. Decker, in a study of the etiology of herpes cornea, states that the fact that a hypertrophic catarrh of the nose co-existed, and that the recurrent attacks of keratitis were preceded by an acute exacerbation of the nasal trouble, which grew less intense after appropriate treatment of the nasal mucous membrane. With us on the Pacific coast, where catarrh is prevalent, patients complain of burning and smarting of the eyes; the conjunctiva is inflamed. By appropriate treatment to the nasal trouble the eye symptoms disappear.

In conclusion, I would say that in all ocular troubles, remove the cause, whatever it may be, syphilis, rheumatism or other debilitating and lowering dyscrasia. We must remember that it is not only our province to gain knowledge wholly from a single organ and direct treatment to the same, but we must study the general condition of our patient and see if we can not find a cause for the local change.

## THE PROSTATE.

JOHN B. MURPHY, A.M., M.D.

Professor of Surgery, Northwestern University, Chicago Post-Graduate School and Hospital, and Chicago Clinical School.  
CHICAGO.

(Concluded from page 749.)

### PROSTATECTOMY.

It is very gratifying to note the advances that have been made by the medical profession in the operative treatment of prostatic enlargement in very recent times. Even so modern a man as Sir Henry Thompson said that he did not believe it was possible to operate on a case of enlarged prostate and have a result that would permit him to discontinue his catheter and still be able to empty his bladder and retain his urine; now we know that these results are of daily occurrence.

The indications for prostatectomy are: 1, prostatic enlargement to a pathologic degree, i. e., sufficient to prevent urination or cause large residual retention; 2, painful and frequent urination; 3, cure for catheter life; 4, cure for secondary cystitis; 5, for the relief of pressure on the rectum; 6, it should be the operation of election where the patient is in condition to withstand the operative procedure and the local general conditions are favorable. The operation should not be considered nor used as a last resort. Local or spinal anesthesia should be preferred in selected cases.

*Suprapubic Prostatectomy.*—Dr. William T. Belfield of Chicago deserves the honor of being the first to follow a deliberate plan for the removal of the middle lobe through a suprapubic incision. This was not an acci-

dent, as suggested by Mr. G. Buckston Browne, but was a deliberately planned and executed operation, as was well known to many of the Chicago profession at that time; the honor is incontrovertibly his; while Dittie's operation was not deliberately planned and executed, but was done in an emergency. Mr. A. F. McGill laid down more definite indications and lines of procedure three years after Belfield's original work, although we believe it can be said that McGill had no knowledge of the Chicago surgeon's technic at the time he performed his first operation.

The suprapubic route was the one uniformly followed in my ten years' service at the Alexian Brothers' Hospital. Either enucleation or cauterization was accomplished through a suprapubic opening, by the aid of curved scissors, Kocher dissector, volsella forceps and the index finger. The middle lobe was readily and easily enucleated, but the enucleation of the lateral lobes through the suprapubic route was always a difficult, bloody, dark and unsatisfactory procedure, though many times very gratifying in its relief to the patient. In this technic there is practically no danger of opening the peritoneum, as the base of the prostate is situated fully half of the length of the bladder below the most dependent portion of the vesico-rectal folds, and is very movable at that point. There is danger, however, of lacerating the rectum.

Dr. Charles H. Mayo favors the suprapubic enucleation of very large middle and lateral lobes, and believes that the technic is more simple and the results more favorable by this procedure, using suprapubic, or suprapubic and perineal, drainage, according to individual indications.

Proust<sup>15</sup> describes an elaborate technic for a subtotal prostatectomy with subsequent suture of the pedicles. The vasa deferentia and the slit in the urethra are also sutured, while a catheter is left in place. The suturing of the vasa deferentia or seminal vesicles would seem to us a difficult task. Mr. P. F. Freyer,<sup>16</sup> commenting on injury to the seminal vesicles, considers that it is a matter of little importance what becomes of the ducts and pays no attention to them. In speaking of hemorrhage, he claims in suprapubic operations that when the gland is enucleated from the capsule there is little hemorrhage.

Dr. Ramon Guiteras<sup>14</sup> collected 153 prostatectomies, by various methods. Of these 110 recovered, 72.3 per cent.; 25 died, 16.4 per cent.; 17 were failures, 11.2 per cent.; and he concludes that the results in those that recover from prostatectomy are better and more permanent than those following prostatotomy. He believes, however, that great care and judgment must be used in the selection of cases, and submits the general rule that "the large glands are favorable for enucleation and the small ones are best treated by prostatotomy; and if the kidney be diseased, either medically or surgically, the Bottini should be resorted to."

Eugene Fuller<sup>17</sup> favors the suprapubic route for the large prostates, and believes that the operation of enucleation can be performed cleaner and safer in that way; but, where the bladder wall is hypertrophied, he considers it much easier and safer to use the perineal operation.

From the 15 cases of suprapubic prostatectomy reported by Dr. Hugh H. Young,<sup>11</sup> there were two deaths, neither of which, however, can justly be attributed to the operation. The ultimate results from the suprapubic operation were very favorable. In this number he classes 11 as "complete enucleation of the prostate." (I believe,

however, he means enucleation of the lateral and posterior lobes and not a complete prostatectomy.) Ten of the 15 were classed as cures and two still suffer from cystitis.

Dr. Floyd W. McRae<sup>11</sup> strongly favors the suprapubic operation, and reports three successful cases. He considers there are special advantages in his ingenious "parachute" drainage method. One of his operations was on a case previously treated by the Bottini plan.

Mr. Harold L. Barnard<sup>18</sup> thinks that the success following enucleation of the prostate for adenomatous hypertrophy, which he considers the most suitable type, is not equaled by any other method of treatment, although he prefers the suprapubic method.

Dr. William N. Wishard<sup>6</sup> strongly favors the suprapubic Belfield-McGill operation, as modified by Fuller and Alexander. He believes it is the most direct means of attack, and gives the best results, as expressed in the following: "If the suprapubic operation has been thoroughly done, and the obstruction all removed, the patients afterwards are assured of more perfect function than by any other method." He thus expresses himself concerning the perineal operation: "The operation may be regarded as limited to drainage operations and to small pedunculated growths, and to the division of collar-shaped enlargements of small size."

*Perineal Prostatectomy.*—Dr. Syms<sup>19</sup> prefers the perineal route, because it appears to him most direct. He believes<sup>20</sup> that the median perineal incision should be made and considers that he derived great advantage from his prostatic retractor in the twelve cases in which he used it. He favors the removal of the left lobe first, the middle lobe second and the right lobe last, and the use of a steel sound every third day after the operation. He forcibly advocates the early operation. He operated on 9 cases; all recovered; in 8 there was complete restoration of function.

Dr. J. W. S. Gouley<sup>20</sup> favors the perineal route. The retractor of Gouley<sup>21</sup> appears to have many advantages, although I have not used it, as the hooks are so much more readily applied.

Dr. John A. Wyeth<sup>22</sup> believes the perineal operation the one of choice. Dr. Alexander agrees in this view but makes the suprapubic incision so that he may force the prostate into the perineum. This is not necessary where the hooks are used, and the capsule and deep perineal fascia properly divided. Most of Dr. Alexander's patients were out of bed in five or six days. No aged patient, after any operation, should be allowed to lie flat on his back. He should be placed in a sitting position immediately, should occupy the recumbent position at night and should be out of bed as early as the fourth or fifth day.

Dr. Alexander Hugh Ferguson<sup>11</sup> reported six cases at the Atlanta meeting, in which he removed the prostate by morcellement. He claims advantages for this method, and has a prostatic forceps so constructed as to "bite" out fragments of the prostate without danger of injury to the surrounding parts; he also has an intravesical depressor which he believes adds much to the ease with which the operation is performed. His six patients made good recoveries. He also calls them complete prostatectomies while I believe he means lateral and posterior prostatectomy, allowing the portion of the prostate known as the "isthmus" anterior to the urethra to remain.

Dr. James Bell<sup>23</sup> beautifully illustrates with a case, a type of prostatic enlargement in which the Bottini

operation would have served no purpose, and in which a prostatectomy produced an ideal result.

Dr. Charles Whallen<sup>24</sup> favors spinal anesthesia for prostatectomy.

By the perineal operation the wall of the bladder should not be divided nor torn, but the posterior wall of the prostatic urethra should be removed. The urethra should never be opened primarily, and the prostate should never be shelled away from the bladder from before backwards, but always from behind forward, dividing the isthmus as the prostate rolls off from the bladder. To favor this I have used, with the ordinary deep lateral retractors and Sims speculum as a posterior retractor, the hooks shown in Figs. 10 and 11. The hooks are utilized, 1, to draw the prostate into the field and retain it there; 2, to evert the prostate while it is being detached from above downward from the bladder wall.

It is entirely unnecessary in the operation of prostatectomy to remove the whole anatomical structure, as is claimed by Freyer,<sup>25</sup> as the anterior portion of the prostate, or isthmus, never shows any material encroachment and never produces urinary obstruction. It can, however, be as easily removed, if the entire enucleation be desirable, by the perineal route as by the suprapubic, if the hook retractors be used as in the drawing. The

Figure 16.

From Case 7, shows lobes attached to each other. Reduced one-half.

hemorrhage is very much less by the perineal than by the suprapubic route.

**CASE 1.**—Mr. E. W. W., aged 55; occupation, financier; was referred by Drs. Henry Hooper and Archibald MacLaren. He was admitted to Mercy Hospital May 16, 1901, and operated on May 18, 1901. He was discharged June 26, 1901. Family history was negative.

**Personal history:** He has had specific urethritis; stricture followed; cured.

**Present illness:** Three years ago he began to suffer from increased nocturnal micturition, not associated with pain. This continued increasing in frequency and rest at night was much disturbed; then the frequency of urination in daytime became markedly increased. Finally, about two years ago, the catheter was first resorted to, which was used only every second or third day in the beginning. The vesical irritation, however, became greater and the quantity of pus in the urine increased until daily vesical lavage was resorted to by the attending physician, the catheter being used several times a day for the relief of urinary retention. A portion of the urine could be voided by strained efforts, leaving about three ounces of residual urine. These symptoms continued up to time patient was admitted to the hospital; he was entirely incapacitated for work.

**Examination:** Urine examined shows a trace of albumin, some blood and a large amount of pus. Urea, 1.8 per cent.; sp. gravity, 1024. With difficulty a sound was introduced into the bladder. Prostate was very much enlarged;

left lobe largest, median lobe pressed markedly backward. Patient is emaciated and very neurotic.

**Operation:** Usual preparations; saline cathartic and enema. 1. Lithotomy position. 2. Ferguson's prostate staff introduced into bladder. 3. Fuller's semilunar incision in perineum, through perineal tissues up to membranous urethra, extending laterally to rami and from lower margin of scrotum in center to level of anus at external ends. 4. With finger in rectum, tissues between urethra and rectum were incised sufficiently to bring prostate well into view and free it entirely from rectum. 5. Prostate was pressed well downward and forward by means of staff in bladder. Capsule of right lobe was divided parallel to urethra and shelled off; right lobe grasped with volsella and carefully drawn down and dissected until the dissecting finger passed over the base, and then the prostate was liberated from bladder, from base to apex of lobe, and amputated. 6. Left lobe was treated likewise; a small rent was made in the prostatic urethra during the dissection. 7. Two small median lobes were then shelled out. 8. Tube placed in bladder through perineal opening and soft rubber catheter inserted through penis; cavity packed with gauze. 9. One side and apex of incision sutured with silkworm gut. 10. Hemorrhage was slight. 11. Dressings and bandage.

Patient returned from operating room, pulse 82, complained of some smarting pain; was placed in a semi-sitting position, 40 degrees.

May 19: Pulse was 96, temperature 99.6. Patient rested fairly well during night; no hemorrhage to speak of. May 20: Pulse 90, temperature 100; rested fairly well. Good drainage through both catheter and perineal tube.

May 28: Pulse 88; temperature normal since May 20. Urine passed through tube 715 c.c., alkaline, sp. gravity 1015, cloudy; few hyaline casts, round, oval and spindle cells. Numerous red blood corpuscles. Pus cells numerous; bacteria present. May 29: Pulse 88, temperature 98.2. Tube became obstructed and catheter also; latter was removed.

June 1: Pulse 98, temperature 100. Considerable pain in lumbar region. Tube removed and permanent catheter inserted. Patient has a mild pleuritic friction sound. June 4: Pulse 86, temperature 98.6. June 7: Pulse 80, temperature 98.6.

June 9: First voluntary urination through urethra; the day following practically all urine passed through this channel; full control, and painless. Patient is doing well; sitting up. June 17: Pulse 76, temperature 98.6. Patient is sitting up daily; 1320 c.c. urine voided in last 24 hours. Perineal wound healed. June 23: Pulse 78, temperature 98.6; patient went for a drive; feeling well. Amount of urine collected in 24 hours, 1375 c.c.

June 26: Pulse and temperature normal. Patient was discharged feeling well; has good control over bladder; urinates every two to four hours in daytime, but is not disturbed at night; no residual urine. Urine: sp. gravity 1005; urea .9 per cent.; no albumin; granular renal cells; few pus corpuscles. Not the slightest pain in urination.

February 4, 1902: Patient has perfect urinary control; can sleep the entire night without urinating. He says his urinary apparatus feels like it did when he was a boy.

**CASE 2.**—Mr. J. S., married, aged 54, merchant, was sick seven years; diagnosis of prostatic hypertrophy.

He was admitted to Mercy Hospital July 3, 1901, and operated on July 13.

**Family history:** Father died of tumor in throat in 1861. **Personal history:** Patient was born in Germany, but lived 44 years in America. General health was always good; appetite good, bowels regular.

**Past illnesses:** He had an infection in arm when 16 years old, and has running sore at present as result of same; chronic dysentery in 1865.

**Present illness:** For past seven years patient has been troubled with painful urination and inability to empty bladder. For past five years there were times when patient could urinate quite freely, but cold or exposure would make it extremely difficult. Two years ago he began catheter life, continuing it for thirteen months. He then received some electric treatment and dispensed with the catheter, although urination

was very difficult and painful. Early this spring the symptoms increased in severity. He resorted again to the catheter, passing considerable pure blood at times. Patient states that as far back as seventeen years his bladder has been weak, and he did not have proper power of expulsion; has suffered extremely in an effort to abandon the catheter, using it but once in three weeks. The prostate is very much enlarged and almost fills the pelvis.

July 12: Chemical examination reveals a trace of albumin. Microscopic examination shows pus in quantity. Residual urine  $3\frac{1}{2}$  ounces.

July 13: Operation after usual preparations. 1. Lithotomy position. 2. Ferguson sound introduced into bladder and held in position throughout operation. 3. Y-shaped incision as in Case 1, through perineal structures until prostate was reached. 4. Posterior broad Sims and narrow lateral retractors inserted; wound held wide open. 5. Circular incision through capsule of right lobe, which was shelled out from above downward by blunt dissection with the finger, the isthmus divided with scissors, and removed en masse. Same procedure for left lobe. 6. Middle lobe removed with scissors; posterior portion of prostatic urethra removed with gland. The bladder retained the urine and a large rubber tube was inserted into it through the perineum. Wound packed with gauze; tube secured to tissues with silkworm gut; permanent catheter inserted through penis into bladder. There was considerable hemorrhage from the left side, which was controlled by a 6-inch hemostatic, which remained for twenty-four hours.

Patient returned from operating room in good condition: pulse 104, temperature 97.4; strychnia sulph. and spts. amm. arom. were the only medication. See Fig. 13, Case 2.

July 15: Temperature 100.8, pulse 90, sixty hours after operation, then normal until July 26. Occasionally an infusion of tritium with cathartics sufficient to keep bowels open, and general diet. July 23: Perineal drain removed. July 25: Catheter removed. August 1: Temperature 102, pulse 120; patient in great pain, caused by a mild epididymitis.

August 3: Temperature dropped to 99.2, pulse to 100. Patient passed some urine through urethra. Aug. 9: Passing all urine through urethra and can hold it as long as two hours. Perineal wound closed. Aug. 12: Temp. 99, pulse 100. Night sweats. Amount of urine, 700 c.c. Sp. gravity, 1017; urea 2 per cent.; trace albumin. Some squamous epithelium; some pus cells. Testicle still painful and somewhat swollen. Aug. 18: Temp. normal, pulse 80.

August 22: Patient is discharged, with full control of urine and practically no pain in urination; Dr. R. H. Foster of Le Mars, Ia., reports as follows, Jan. 30, 1902: "The muscular fibers of the bladder have completely regained their lost tone, and he can propel the stream to a normal distance. The frequency of micturition, especially at night, has disappeared to such an extent that during the past three months he has not had any call to get up at night except while suffering from the orchitic attack, which I mentioned to you in my former letter. The power of retention has returned to a normal condition; also the lumen of the stream, which is remarkably full in volume and is neither flattened, forked or twisted."

CASE 3.—Mr. A. J., aged 67, merchant, was sick 2 years. He was admitted to Mercy Hospital Aug. 24, 1901, with diagnosis of prostatic hypertrophy and cystic calculi. Family history is negative. Personal history: Suffered severely from constipation. Past illnesses: He had malaria in 1860, and sciatica at intervals for past ten years.

Present illness: Began two years ago with frequent desire to urinate and vesical tenesmus; burning in perineum, hypogastrium and glans penis, which was relieved on urinating.

Patient has been compelled to use catheter at intervals for past nine months. Three months ago a few drops of blood appeared at the end of urination. In the past few weeks patient has suffered severely from vesical spasm, which was not relieved by emptying the bladder. The prostate is very much enlarged. Stone detected.

August 24: Reaction of urine acid; sp. gravity 1013, small amount albumin; urea 1.4 per cent. Microscopic; epithelium, a few squamous cells; many red blood cells; pus in quantity. Residual urine 10 drams.

August 25: Operation, following usual preparations. 1. Lithotomy position. 2. Ordinary steel sound introduced into bladder and kept there. 3. Incision as in previous cases. 4. Prostate exposed and rectum entirely freed. Right lobe of prostate brought into view; capsule incised parallel with urethra and right lobe enucleated, drawn down with volsella forceps and removed. Left lobe with portion of urethra then removed; middle lobe was easily enucleated. 5. Forceps introduced into bladder and stone removed without difficulty. 6. Rubber catheter introduced through urethra into bladder and secured. Large rubber tube introduced into bladder through perineum and perineal wound packed with subiodid bismuth gauze, to suppress the oozing. 7. Deep sutures of catgut to bring structures into apposition. 8. Interrupted silkworm gut sutures for partial closure of incision. 9. Dressings. See Fig. 12.

Figure 17, from Case 7, shows the lobes separated. Reduced one half.

Patient returned from operating room in good condition. After nausea had ceased he was put on urotropin, 7 grains, t.i.d.; liquid diet.

August 27: Patient rested well; pulse 102, tempt. 101. Wound dressed; some oozing; bladder irrigated with solution of boric acid. Aug. 28: Pulse 80, tempt. 100; patient had some pain; wound dressed. Urine in bottle 720 c.c. Considerable urine lost on dressings. Aug. 29: Drainage free; patient easy; 900 c.c. urine. Aug. 30: Pulse 88; tempt. 98.8. Urine 1000 c.c. through tube.

August 31: Pulse 88, tempt. 99; patient delirious short time. Amount of urine 2000 c.c.; reaction acid; sp. gravity 1015; turbid; urea 2.4 per cent.; albumin in quantity. Small squamous epithelial cells; few red blood corpuscles. Considerable pus; bacteria present.

September 1: Pulse 84, temperature 98.8. Patient rational; suffering pain and stinging sensation. Sept. 4: Wound looks healthy. Pulse 80, temperature 99.6. Sept. 10: Pulse 78, temperature 98. Perineal sutures removed. Sept. 12: Pulse 70, temperature 100; perineal wound closing rapidly and looks healthy. Sept. 14: Patient had chill. Pulse 88, temperature 102. Syphon attached to catheter.

September 15: Pulse 80, temperature 98.8. Right testicle swollen, tender and painful; left epididymis indurated, which accounts for chill yesterday. Applications of ice. Scrotum suspended. Sept. 16: Pulse 78, temperature 99. Urotropin, grains 5, t.i.d. Swelling in testicle reduced. Urine examination: Sp. gravity 1015, clear; urea 2.2 per cent; numerous pus cells, otherwise normal. Sept. 22: Pulse 78, temperature

100; patient rested well. Urine ceased to pass through perineal wound, allowed up daily. Nov. 7: Pulse 72, temperature 99; some pain but has control of urine. An abscess formed in perineum which required drainage.

CASE 4.—Mr. W. S. M., aged 58, married, farmer, was sick 8 years. He was admitted to Mercy Hospital Nov. 4, 1901.

Family history: Father died of rheumatism and heart complications at the age of 49 years. Mother died of Bright's disease at the age of 68. One sister died of throat and lung trouble, probably tubercular.

Personal history: Always moderate user of whiskey. Beer always seemed to aggravate present trouble. About nine years ago began to get up to urinate at night, but for last three or four years has been getting up three or four times; would pass small amount of urine each time. During first few years of the trouble urine showed heavy brick-red deposit on standing, but of late years has been clearer, with more offensive odor. Past sickness: Has had a right side inguinal hernia since 21 years of age; has had hemorrhoids for many years, but they have been worse since present trouble began, due to constant straining on urination.

Present illness: Patient was thrown from a horse and fell astride a ridge of dirt in the road, eight years ago. There was considerable tenderness in the perineal region after this injury. Skin was not broken, but parts were bruised. He was put to bed; had chills and fever for next twenty-four hours. He only remained in bed for a day or so and passed his urine,

Figure 18 shows transverse section of right lobe from Case 7, illustrating the numerous small myomata in the upper portion and the hyperplasia in the lower.

at the time, with effort. There was no blood in urine, nor in stools. Since that time he has been troubled almost constantly with bladder trouble. There has been vesical tenesmus when on feet; if in bed he can hold urine longer. Patient can start flow of urine without much pain, but at the end of the act there is a dull burning and a dribbling for some time. When trying to hold urine any length of time there is a sudden loss of half an ounce or so before he can control it. For a long time patient has had a cutting pain in end of penis when through urinating. The straining at the end of urination brings down a small tumor mass in the rectum not unlike a hemorrhoid. All of above symptoms have been getting worse for past four or five months. He was catheterized but once, and that last summer, by a home physician, to see if there was retention of urine. He never has had any chills or fever since injury, eight years ago. Patient has never been confined to bed, but has never been able to work; for, as soon as he walks or rides, he has the desire to urinate, with the pain following. State of nutrition good; appetite good; bowels constipated. Examination: Prostate enlarged to second degree; stone detected behind the prostate.

November 6, 1901: The patient was prepared for operation in the usual manner: A sound revealed size of stone in the bladder; the prostate was very much enlarged. Technic same as in previous cases, except the staff was dispensed with after the capsule was exposed, and the prostate drawn forward with

the hooks shown in Fig. 8. The hooks were found of great assistance, as they permitted an easy separation of the base of the prostate from the bladder, and rendered the staff needless. The stone was extracted after the removal of middle lobe. See Fig. 14.

November 6: Nothing to record but an intermittent pulse, which quickly responded to strychnia. The highest temperature and pulse rate were 101.4 and 104 respectively. Nov. 7: Patient rested well; complained of some pain in bladder. Average temperature and pulse same as previous day. Nov. 10: Patient resting well. Temperature 99.6, pulse 89; urine 600 c.c. through tube. Nov. 11: Temperature 98.8, pulse 93; wound dressed with dry dressing; saline cathartics. Urine 690 c.c.

November 12: Temperature 100.8; pulse 99. Patient resting well; packing removed; no pus; catheter irrigation; all drainage found free; scrotum somewhat edematous; left testicle enlarged and tender; right slightly enlarged.

November 13: Temperature 101.5, pulse 97. Bladder irrigated. Perineal drain removed Nov. 14: Temperature 99, pulse 82. Drainage free; urine 900 c.c. Nov. 15: Temperature 98.6, pulse 83; resting. Urine 100 c.c. through catheter. Nov. 16: Temperature 98.9, pulse 81; patient perfectly easy; urine 2160 c.c. Nov. 17: Temperature 99, pulse 76. Resting. Catheter removed.

November 20: All urine passed through urethra. Perineal wound practically closed. Dec. 4: No vesical pain; he can hold urine four to six hours, and does not have to get up at night. Microscope reveals small number of pus corpuscles in urine.

Figure 19, drawing from cut surface of middle lobe of prostate from Case 7, showing about the same histologic structure as the lateral lobe with distinct loosely attached capsule.

CASE 5.—Mr. P. T., aged 62, retired farmer, was sick 4 years and admitted to Mercy Hospital Dec. 2, 1901.

Personal history and previous illnesses: Usual diseases of childhood. Malaria many years ago. La grippe seven years ago, since which general health has not been as good as before, though fair. Appetite is good. Bowels somewhat constipated for past four years. No bladder nor kidney symptoms previous to present trouble. Venereal history is negative.

Present trouble: About four years ago patient began to have frequent urination; four times nightly, latterly eight or ten times; small amount of urine passed each time; total amount of urine passed was probably normal. Was treated by irrigation of bladder and local applications of electricity. Took diuretic tablets. About three years ago was unable to urinate and had catheter passed, but has not needed catheterization since until ten weeks ago, when he catheterized himself and has done so several times since that time. For past ten weeks he has irrigated his own bladder daily or oftener with boric acid in boiled water. About eight weeks ago he caught cold and had two quite severe chills followed by temperature of 103 to 104 lasting a day or two, and was confined to bed a week or more. Two days ago patient had slight chill and temperature of 100. Patient complains of no severe pain, but has had some discomfort about perineum and pain running into penis, aggravated by walking, standing and sitting. He has less discomfort when he drinks much water;

has burning pain on urination, especially when passing small amounts of concentrated urine; has noticed brick-dust sediment in urine at intervals; has not noticed pus.

December 5: Pulse 84, temperature 98.8; 250 c.c. urine during night. Bladder irrigated with 1 per cent. sulpho-carbolate sodium in 1 to 4000 sol. formalin. Urinalysis: sp. gravity 1016; urine turbid; urea 2.4 per cent. Phosphates increased; indican present; no casts or albumin; many pus cells.

December 10: Bladder has been irrigated daily since admitted. Tonics and diuretics administered, also urotropin. The prostate extends backward, pressing the rectum, and the lobes seem to fill the pelvis to the rami on either side. A stone was detected.

December 11: Operation: 1. Ether anesthesia; lithotomy position. 2. Inverted Y-incision in perineum from posterior fold of scrotum to the rami, on a level with anus. 3. With finger in rectum, the perineum was divided on either side of the corpus cavernosum until the prostate was reached and then the central septum was divided. Beak lateral retractors and Sims posterior retractor were used to expose the field of operation. 4. Capsule of gland incised parallel with urethra and separated from gland by blunt dissection, with finger and Kocher dissector. 5. Right lobe is grasped with small hook retractor and drawn down and out, and then grasped with second hook retractor and rolled forward and separated from the bladder down to the isthmus, where it was divided: left lobe treated in like manner. Middle lobe removed, with small portion of posterior prostatic urethra. Anterior isthmus not disturbed. The stone was then removed with a lithotomy forceps. 6. Rubber drainage tube passed into bladder through perineal opening; this was surrounded with bismuth subiodid gauze as a packing. 7. Wound closed except on left side with silkworm gut: left side left open for passage of tube and gauze. 8. Dressings and bandages.

Patient returned from operating room and was placed on back rest at angle of 30 degrees. Pulse was 78, low tension; temperature 97.4. He rested quietly and comfortably. Siphon and bottle were attached to drainage tube in perineum. Photograph of prostate, Fig. 15, Case 5.

December 12: He rested very well; pulse 96; temperature 99.4. He drinks considerable water. Dec. 13: Pulse 88, temperature 99. Patient is drowsy and comfortable. Dec. 14: Pulse 82, temperature 99.2; quite comfortable; free drainage.

December 15: Pulse is 84, temperature 98.4. Patient quite comfortable. Dressings changed three times; some of the packing removed. He voided 1530 c.c. urine through tube, and slept well. Dec. 16: Pulse 88, temperature 98.8. He voided 900 c.c. urine through tube. Slept ten hours; feels quite comfortable. Dec. 17: Pulse 88, temperature 99; 1200 c.c. urine through tube. Slept ten hours. Dec. 19: Pulse 80, temperature 99; 1500 c.c. urine through tube. Perineal tube and packing removed. Slept ten hours.

December 22: Pulse and temperature were normal since 19th. Catheter passed through penis. Passes small portion of urine through urethra. Wound in excellent condition. January 1: Catheter with stylet passed. He passes urine by both perineum and urethra. Jan. 5: Wound is healing rapidly. No urine passes through perineum. He is up and walking around room. Patient feels quite well; has control of urine. Jan. 18: All urine passes per urethram; full control. Patient is discharged feeling quite well; can sleep all night without urinating. Urine acid, sp. gravity 1014; trace of albumin; some pus corpuscles.

CASE 6.—Mr. L. D. R., aged 70, widower. Father died at 88 of strangulated hernia. Mother died at 66 of cancer (?). Two brothers died of prostatic disease, with complications, aged 77 and 82. One brother died of pneumonia at 77. Four brothers living and in good health, aged 60, 64, 73 and 77. Three sisters died of female diseases, ages 50, 52 and 53. He has three sisters living and in good health, ages 60, 68 and 75. He came under observation of Dr. F. A. Turner, Sandwich, Ill., September, 1901, with symptoms of prostatic inflammation, which continued for several days until there was a free discharge of pus from rectum, when the symptoms subsided. He did not see him again until Nov. 11, 1901, when present attack began with severe pains in the prostate and a constant desire

to pass water, being able to void but small quantities of turbid urine which contained considerable pus. On November 14 complete retention came on, and, notwithstanding the fact that a large amount of pus was discharged from rectum on night of 14th, the retention continued complete until the 22d, the date of the operation. He was catheterized every three or four hours. Amount of residual urine not obtained.

Operation was made December 20. Technic was same as in previous operations. Abscess was found in left lobe. Both lateral lobes were very much enlarged. Lateral and middle lobes were removed.

Post-operative history (kindly furnished me by Dr. Turner): During first six days after operation pulse varied between 114 and 99; temperature between 99 and 97.6; 1/30 gr. strychnia was given hypodermically every four hours. Liquid diet given every two or three hours. Bowels tympanitic and greatly distended during this period, for which he was given tinct. menth. pip. and asafetida, each 1 oz., in 3 pints of water through colon tube, with good results; this was repeated as required.

Bladder was irrigated daily through the drainage tube and the iodoform packing was removed on the sixth day. From the sixth to fourteenth day pulse and temperature were normal. Pus discharged freely from the tube, which was removed on the fourteenth day. Daily irrigation was continued and a fresh piece of iodoform gauze was inserted after each washing. Eight hours after the tube was removed (fourteenth day) he urinated per urethram. Strychnia was given per mouth up to the 20th, when it was stopped.

On December 20 urine passes through urethra and the bottom of the wound is apparently healed. The external portion of the wound is still kept open with a small piece of iodoform gauze. Urine is still turbid; contains pus and is ammoniacal; sp. gravity 1010. During the first week following operation there was a double epididymitis, which was relieved by elevating the scrotum and applying hot fomentations. Dec. 24: Patient is sitting up now and taking solid food. Jan. 5, 1902: Since last letter there has been a free discharge of pus from perineum.

January 16: "The wound in perineum has completely closed. He has control of his urine, which is clear and free from pus. He is not disturbed at night, and has fully recovered. I discharged him Jan. 14, cured."—Turner.

CASE 7.—Mr. C. G., aged 52, laborer, single, was admitted to Cook County Hospital Dec. 7, 1901.

Previous history: States he was perfectly well up to four days ago.

Present illness: Four days ago began having a dull pain in abdomen, which gradually increased until he was compelled to quit work and go to bed early in evening; could not sleep that night; next morning vomited three or four times. He has had no appetite since then and "has not been able to keep anything in stomach." About the time he began vomiting he commenced having trouble in urinating; would have desire to urinate, but could evacuate only a very small amount, after severe straining. This desire to urinate would come on a dozen times daily, always with same result. Says he never had previous urinary trouble of any kind. Denies all strictures, gonorrhea, etc. Bowels have not moved for four days. There is no pain in penis; no cough; no pain in chest; no headache or epistaxis.

On closer questioning admits gonorrhea several times and says he has had a stricture. Statements seem unreliable. Denies syphilitic infection. Denies all previous illness. He was hard drinker for thirty years; smokes to excess now. Friends of patient say that recently he has been having "flighty" spells. Patient, himself, says he is "silly" at times and has been since his parents died, thirty-five or forty years ago.

Examination shows man past middle age; poorly nourished; in no apparent pain; indifferent to surroundings; mentality poor, so that little dependence can be placed upon his statements. Pupils equal, but retract slowly to light. Teeth covered with sordes; breath foul. Chest: heart and lungs negative. Tumor mass extending from pelvis above umbilicus, half way to ensiform; appearance that of seven months' preg-

nancy; uniform dulness over this mass; no fluctuation obtainable; surface smooth; auscultation negative; tumor disappeared after catheterization. No stricture; slight urethral discharge, in which are gonococci. A very much enlarged prostate, sensitive to pressure but not fluctuating. Has all the external manifestations of an intense cryptogenic infection. Patellar reflex is increased; ulnar reflex diminished.

December 7: Catheterized 11 a. m.; 64 oz. urine obtained; 5 p. m. 58 oz., 11:30 p. m. 52 oz. Dec. 8: Catheterized noon, 45 oz. urine. Temperature 98.4, pulse 68. Dec. 9: Catheterized, 32 oz. urine obtained. Permanent catheter put in. Urinalysis: Sp. gravity 1018; reaction acid; no albumin or sugar. Leucocytes numerous; granular and hyaline casts of large size. Dec. 10: 38 oz. of urine removed. Permanent catheter removed.

December 12: Gonococci found in smear from urethral dressings. Nothing of consequence to note up to date of operation. Patient was repeatedly catheterized and was kept on general diet with frequent saline cathartics. Temperature and pulse ranged near normal, but presented all the time a low, typhoid condition, apparently from some hidden sepsis.

Operation was performed December 20. 1. Lithotomy position. 2. Semilunar incision from one ramus of ischium to the other. 3. Skin reflected from apex of incision down almost to rectum, leaving triangular denuded space. 4. Fascia divided in median line down to urethra and prostate, which are

night. Temperature 101, pulse 100. Dec. 28: Temperature 101, pulse 102. Perineal drain removed. Dec. 29: Slept but little during night. Refused medicine. Temperature 100.4, pulse 100. Dec. 30: Did not sleep during night. Temperature 100.4, pulse 100.

December 31: Slept fairly well during night. Temperature 99, pulse 88. Strych. sulph., grain 1/30. Pot acet., grains 10; urotropin grains 5, twice daily; light diet. Catheter passed through urethra; bladder empty. Jan. 1, 1902: Patient slept fairly well during night. Temperature 99.4 pulse 98. January 2: Rested fairly well during night. Podophyllin et calomel, each gr. 1/2. Temperature 99, pulse 98. Light diet. Jan. 3: Temperature 98.8, pulse 88. Jan. 4: Slept at intervals only. Temperature 98, pulse 96. Jan 6: Permanent catheter. Jan. 10: Catheter removed; perineal wound almost healed and urine passed through urethra. General condition about the same as before the operation. All vesical symptoms disappeared.

CASE 8.—Mr. H. H., aged 66, wood-worker, was admitted to Mercy Hospital Dec. 16, 1901. Family history is negative. Personal history: Patient has always enjoyed good health until present illness, with the exception of a month's illness with bowel trouble twenty years ago. Patient's work has not been especially heavy, but it has been often in unheated rooms. Drinks wine and beer occasionally. Venereal infection denied. Constipation since onset of present trouble.

Present illness: Ten or fifteen years ago patient began to have frequent urination, passing only small amount each time. Some discomfort and a feeling that the bladder was not empty often followed urination. This condition was intermittent; was less common in summer than in winter, and was aggravated by exposure and by constipation. This continued, gradually becoming more annoying last summer. It was characterized by more discomfort than ever, and increased frequency of urination. Three weeks ago patient passed some blood, clotted and fresh, with his urine; was unable to pass water for a week thereafter, and catheterized himself from that time until now. The blood has disappeared, and he can not empty his bladder without catheter, there being about five ounces of residual urine. He urinates every two or three hours during the day and rises many times during the course of the night.

December 17: Urinary examination shows sp. gravity 1017; urea 1.5 per cent.; few flat and round cells, considerable mucus; pulse 72, temperature 98.4. Dec. 19: Urine in 24 hours 1500 c.c., reaction acid, sp. gravity 1020; turbid, urea 1.3 per cent.; faint trace of albumin; few squamous cells and pus in quantity. Prostate very much enlarged, particularly on left side.

Operation on January 8; usual preparations; ether; lithotomy position. 1. Inverted Y-incision in perineum from junction of posterior fold of scrotum back to the rami at a level with the anus. 2. Rectum pushed back away from prostate with finger and deep retractors used to expose field of operation. 3. Capsule of gland incised parallel with urethra and separated from gland by finger and blunt dissection. 4. Right lobe grasped with small hook retractor and drawn down and out and then grasped with second hook retractor; rolled out from behind forward and separated from the bladder with the finger, and isthmus divided. Left lobe was treated in like manner. Middle lobe was shelled out and removed, with posterior wall of prostatic urethra; isthmus not disturbed. 5. Rubber drainage tube passed through perineum into bladder. Soft catheter passed into bladder through urethra. Strips of bismuth subiodid gauze packed around perineal rubber drainage tube. One hemostatic was allowed to remain. 6. Wound closed except on left side by silkworm gut. Left side

Case 7 (a).—Right lobe shows hypertrophied prostatic tissue firmly attached to the myoma, also the feeble attachment of the middle to the lateral lobe.

located by sound held firmly in urethra. 5. Rectum separated from urethra by blunt dissection and held down by Sims speculum. 6. Right lobe of prostate dissected free, capsule peeled back and sharp hook fastened into prostate; traction and blunt dissection used simultaneously, additional hooks taking fresh holds as the lobe rotated outward; separated from isthmus with scissors. 7. Left lobe excised in same manner, each being about the size of a duck's egg. See Fig. 8. 8. Middle lobe, size of walnut, easily shelled out, tearing posterior urethra, escape of urine. 9. Rubber tube put through this opening into bladder, packed around with gauze, and skin partly closed with silkworm gut sutures. 10. Dressings and bandages.

December 20: Patient returned from operation with pulse irregular and weak; respiration shallow—sighing. Skin warm and dry—cyanosed. Temperature 101, pulse 98. Strych. sulph. grain 1/30, twice daily. Figs. 16, 17, 18 and 19.

December 21: Patient rested fairly well during night. Liquid diet. Pulse 98, temperature 99. Pot. acet. grains 10; urotropin grains 5, twice daily. Dec. 22: Patient slept most of night. Temperature 100.4, pulse 104. Dec. 23: Patient resting well; pulse 98, temperature 99.4. Dec. 24: Patient slept fairly well during night. Pulse 96, temperature 99.4. Dec. 25: Pulse 96, temperature 99. Dec. 26: Pulse 100, temperature 101. Dec. 27: Patient slept only at intervals during

left open for passage of drainage and gauze. Catheter sutured to penis with silkworm gut. 7. Dressings and bandage. There was a moderate amount of hemorrhage. Patient returned from operating room warm and in fine condition. Back rest was placed under patient at angle of 30 degrees. Pulse 78, temperature 97; slight nausea, free perspiration. Prostate about same size and shape as Case 5, Fig. 15.

January 9: Considerable discharge of urine, some blood. Pulse 88, temperature 99.2. Tubes arranged from catheter and drainage tube to bottle. A portion of the packing was removed. Jan. 11: Pulse 80, temperature 98.4; tube and most of packing removed. Patient is resting comfortably.

January 14: Pulse is 80, temperature 99. Pulse and temperature have remained near normal since 11th. Perineal drainage tube and remainder of packing removed. Wound looks healthy. Urine passed voluntarily, principally by perineum. Patient comfortable, sitting up in bed most of the time.

January 16: Pulse 78, temperature 98.6. Urine passes through perineum. Patient rests well and feels comfortable. Jan. 21: Pulse and temperature normal; 270 c.c. urine in bottle. Wound clean and healthy. Jan. 23: Pulse and temperature normal.

Case 7 (5).—Left lobe, shows enormous hypertrophy of prostatic tissue around a small urethra.

Catheter removed; some urine followed through urethra; most of it passes through perineal wound. Patient sleeps well and feels comfortable. Jan. 28: Patient gaining control of urine; most of urine passes through perineum, but quantity through urethra increasing. Jan. 31: Patient can hold urine several minutes after desire to void is felt. Most of urine passes through urethra; small amount through perineal wound. Patient walking about and very comfortable.

February 4: Patient has walked to dressing room. Wound is closing; very little urine passing through it. Control of urine increases daily. Feb. 7: For past three days urine has been very well controlled; almost the entire amount passed through urethra. Occasionally a small amount is forced through perineal wound. Patient feels fine. Feb. 8: A few leucocytes are in urine; acid in reaction. He passes all urine through urethra and has good control.

#### CONCLUSIONS.

1. From the clinical reports and experience, it seems evident that in extreme cases prostatotomy is the operation of election.

2. It appears evident that in the hands of safe, far-seeing, informed practitioners, few cases will now be allowed to progress to this extreme condition before radical means are resorted to for permanent relief. The practice of to-day should be timely practice.

3. Continued use of the catheter is a menace to life, not to mention its discomfort, no matter how favorable the conditions for its performance. The patients all, sooner or later, suffer from cystitis and its sequelae.

4. Prostatectomy gives the best permanent result, and is fraught with very little more danger than prostatotomy.

5. Suprapubic prostatectomy should be limited to exceptional cases of enormous intra-vesical enlargements of the prostate. It appears to us to endanger the sphincteric control more than the perineal operation. It is more sanguinary and the work is more difficult and distant from the operator.

6. The perineal is the most direct and least bloody

route. It admits of a very large opening, and permits the prostate to be drawn quite into the open before it is attacked. It gives the greatest security against injury to the bladder wall and least liability to disturbance of the internal sphincter. It endangers the rectum least and affords the best drainage.

7. It can be best performed through a Y-shaped incision, with a Sims speculum for a posterior retractor. The prostate is drawn out easily with sharp hook retractors, and best separated from the bladder from behind forward. The operation should never be performed in the dark, i. e., through a small incision.

8. It should always be an intracapsular enucleation en masse, allowing the anterior isthmus to remain. The hemostasis may be secured with forceps or a packing of subiodid of bismuth (not iodoform) gauze. The permanent catheter should not be introduced until the perineal drain is removed.

9. The patient should be kept in a semi-sitting position for seventy-two hours after the operation, and

should be out of bed by the fifth day. He should drink large quantities of water from the onset.

10. Anesthetic is sub judice. Phosphate of sodium should be administered to keep the urine acid; and urotropin as an antiseptic. The personal equation must never be lost sight of in operating these cases, and attention to every small detail of the patient's general condition is necessary for the best results.

[I am indebted to Dr. E. F. Brandt, interne of Mercy Hospital, for the excellent photographs.]

### CASE OF TYPHOID FEVER

COMPLICATED BY A THROMBO-PHLEBITIS OF THE LONG SAPHENOUS VEIN, A SEVERE HEMORRHAGE FROM THE BOWEL, INFECTION OF THE CLOT, WITH RECOVERY.

GEO. C. ARMSTRONG, M.D.

CAMBRIDGE, NEB.

A young man, aged 20, of spare build, was seen in the writer's office Aug. 21, 1901. He complained of severe frontal headache, dizziness, ringing in the ears, pains in the eyes, loss of appetite, gurgling in the abdomen, backache, diarrhea, exhaustion and nose-bleed. The tongue was thickly coated, spleen and liver enlarged, gurgling and tenderness in the right iliac fossa, and some cough. Pulse was 72, temperature 102.5.

The patient was given a laxative, sent home to bed, and a sample of urine was ordered for examination. The following day he was seen at his home; temperature was 104, pulse 82 in the evening; urine showed the diazo-reaction of Ehrlich and a diagnosis of typhoid fever was made. Systematic cold sponging was practiced every three hours, a milk and beef juice diet was ordered, at the same time an intestinal antiseptic was continually given. At no time during the treatment was the temperature above 103, pulse ranging between 75 and 85. At the end of the fourth week the appetite became better and some diarrhea which was present all through the sickness, ceased, and convalescence became apparently established. Stimulants in the form of whisky and strychnia were given the patient as there was an altered first heart tone and a systolic murmur heard at the apex.

On September 17 the patient complained of pain in the left calf, which extended upwards along the inner surface of the thigh into the groin. The left testicle was also painful. The upper thigh was some swollen, and the long saphenous vein could be distinctly palpated from a little above the ankle to the middle of the

thigh. There was no swelling of the limb below the knee. The spermatic vein presented the same condition as that of the limb; the testicle was not apparently affected. Coincidentally with the formation of the thrombus, the temperature arose to 105.2, pulse 116.

The limb was enveloped in cotton and a roller bandage applied, and the testicle was supported. Four days after the onset of the phlebitis the temperature was 100.5, pulse 90; some pain existed in upper limb and along the spermatic vein.

In the afternoon of the same day he felt a fulness in the abdomen, saw various colors, was nauseated, sleepy and thirsty, was short of breath and desired to evacuate his bowels. He immediately passed into the bedpan, with much force, two liters of dark blood.

The hips were elevated, morphin and ergotin given hypodermically, ice to the abdomen and perfect quiet ordered. His condition was now one of acute anemia and normal salt solution was injected, a new rubber fountain syringe and an ordinary aspirating needle, which was sterilized by boiling in soda solution, being used. One liter was given under the skin on each side, the needle being inserted a little above and external to the nipple. The effects of the salt solution was quickly noticed, and in six hours the patient passed a full 16 ounces of urine and felt much better. The bowels moved spontaneously the third day after the hemorrhage. The temperature and pulse gradually fell, when one week from the day of his hemorrhage he had a pronounced chill, lasting 40 minutes; temperature 105.5, pulse 135. Profuse perspiration followed. The pain in the limb which had by this time nearly ceased, now became much worse, and varied in severity according as the temperature arose or fell, being worse as the temperature went up.

One week from the day of his first chill, a second came on, lasting as long and was as severe as the first, followed by the most exhaustive sweats; temperature and pulse arose as high as before. The temperature and pulse oscillated as before for ten days, when he had a third chill lasting not quite so long as the first two; sweats again followed. After each chill with rise of temperature the skin presented all over the trunk, especially on the lower abdomen and back, a fine pinhead pustular eruption, which gave the patient much annoyance on account of the itching and smarting. Frequent turning of the patient with bathing and rubbing with alcohol to prevent decubitus was practiced.

Iron, quinin and strychnia were given to help correct the anemia as well as a tonic and stimulant, with a liberal allowance of predigested milk, ice cream and broths, and finally the patient began rapidly to improve; the appetite returned, the temperature and pulse oscillating for one week, and finally became normal and frequently subnormal, when in nine weeks from his initial visit to the office, the patient was sitting up most of the time. He now feels entirely well, having worn a bandage for five weeks after beginning to walk, to help counteract the swelling. The distressing intestinal catarrh, from which he suffered previous to his sickness and which resisted all lines of treatment, is now entirely cured.

The case is interesting from the facts that an apparently moderate attack of typhoid fever is no criterion from which to deduce a prognosis; this case demonstrated beyond a reasonable doubt the value of the salt solution that was used to correct the acute anemia.

## THE PROPER ADJUSTMENT OF REST AND EXERCISE IN THE TREATMENT OF TUBERCULOSIS.

Whether or not we shall ever come into possession of a specific remedy for tuberculosis is a matter for the future to decide. That spontaneous recovery from this disease not rarely occurs is a matter of common observation, so that it must be admitted that under certain favoring conditions the invaded body is capable of generating antitoxic substances that aid in bringing about the result desired. As to the position that tuberculin occupies in this connection there is some doubt. In the hands of those who have used this preparation most faithfully and continuously and, therefore, it is to be assumed, most intelligently, the results have been most gratifying, but tuberculin is a powerful agent and it has shown its capability for evil as well as for good. In the absence, therefore, of a remedy possessing specific curative properties and susceptible of safe general employment, the clinician is forced to depend upon those natural resources by means of which the resistance of the organism to the activities of the tubercle bacillus is increased. The problem, it has been learned, is essentially one of nutrition, and the main factors in its solution are a proper adjustment of air, sunshine, food, rest and exercise. The principles underlying the application of the last two factors have been recently discussed in a practical manner by Dr. Naegelsbach.<sup>1</sup> Here, as elsewhere, there has been a tendency to go to extremes, while, as usual, the correct position is an intermediate one. The question must be decided in accordance with the conditions present in the individual case.

As a matter of course, when the disease is progressive the patient should, as soon as possible, be withdrawn from physical and mental activity and placed under conditions most favorable for rest. If the temperature is but slightly elevated, the patient may occupy the recumbent posture in the open air. Those patients also should be kept in bed who, despite a normal maximum temperature, exhibit in the morning or repeatedly temperatures of collapse, with evidences of advanced lesions and great asthenia. If the temperature, previously normal, rises gradually or suddenly the patient should be put to bed. If in the course of a period of such rest it be found that the patient can lie upon a reclining chair without elevation of temperature he may gradually be brought into the open air. It is necessary, however, that there should be also absence of chills, sweats, marked

prostration and exhaustion and increased cough, of recent inflammatory changes in the lungs and other organs and of loss of weight. In cases of softening with intermittent or remittent fever and normal or approximately normal morning temperature the most rapid results, in accordance with the course of the morbid process, are brought about by rest in bed. Care is necessary on account of the danger of hemorrhage. Transitory slight elevation of temperature is naturally of less significance than elevation persisting for hours.

When the temperature declines regularly in the evening a few tenths from 98.5 or 99 F. the patient may be permitted to remain out of bed until after the evening meal. If the evening temperature remains unchanged or even rises, complete rest in bed in the afternoon should be enjoined. When the temperature is slightly inverted, rest in bed should be continued for a longer time in the morning. In cases in which there is slight elevation of temperature in the absence of evidence of active disease, as, for instance, in patients with old pleurisy or chronic bronchitis or large old cavities, rest on a reclining chair will suffice. Patients with large cavities must exercise greater care than those with so-called apical catarrh; as must also those in whom active lesions are present, especially if attended with many moist râles, as well as bleeders, whether from peculiarity in the local process or from hemophilia. In the presence of hemorrhage to greater degree than blood-streaked sputum, rest in bed should be observed, as a rule, although occasionally the bleeding ceases after the patient gets up and moves about carefully. Beginning pleuritis also demands caution. Rest-treatment will be especially indicated in the case of debilitated, anemic, chlorotic and neurasthenic individuals.

When the patient is permitted to walk he should stop before he becomes tired, should avoid the occurrence of perspiration, should set no limit to his walk so that if possible he makes ascents while fresh. The time for the walk and its length should be determined for the individual case. A patient who has become wholly apyretic may tentatively walk for a quarter of an hour at about 8:30, 11:30 and 4:30, and in the course of a week or two the time may be increased to an hour—that is, three hours a day. Patients with extensive lesions and with fresh cavities should advance more slowly. Greatly emaciated patients who exhibit little tendency to increase in weight should walk but little. Rest should be taken in the intervals of walking and for 20 or 30 minutes before meals. In cases of bronchiectasis, walking up gentle grades is of value to facilitate expectoration. Such walking in moderate degree regulates and strengthens the action of the heart in all cases and frequently ameliorates bronchitis, while strain on the heart does the reverse. Walking should, of course, be interdicted whenever it induces elevation of temperature. In cases in which the morbid process has terminated or in which there is no evidence of secretion careful respiratory gymnastics may be practiced with advantage if the

1. Berliner Klinische Wochenschrift, Feb. 24, 1902, p. 163.

breathing be not full and if pleural adhesions are present. Other forms of physical exercise and eventually some agreeable occupation may be cautiously indulged in as improvement progresses. So far as possible the patient should be spared emotional disturbances such as may result from the responsibilities and activities of domestic life. In the presence of fever even the visits of friends should be interdicted. A certain amount of mental stimulation and recreation is, however, to be generally encouraged.

#### FAMILY PERIODIC PARALYSIS AND ALLIED NEUROSES.

The close study of cases of disease which have at first appeared to be identical has often led to a separation of the original clinical entity into two or more distinct diseases each having its own peculiarities. Since Bretonneau wrote his classical memoirs on diphtheria this disease has been recognized as one entirely separate from other pseudo-membranous inflammations of the throat, and with the aid of modern bacteriologic methods the differentiation of the various forms of angina upon an etiologic basis has been carried still further. Exhaustive study has always been fruitful in the separation of diseases which were previously confused. On the other hand, the thorough study of individual clinical diseases has often resulted in the discovery that what had appeared to be entirely different conditions may have much in common and may even be different phases of the same general disease. This is exemplified in a group of paroxysmal neuroses of which migraine and epilepsy are the more common members, and family periodic paralysis the unusual one. In a recent report of the first case of family periodic paralysis observed in England, Singer<sup>1</sup> has again directed attention to this peculiar and rare disease. Although cases had been previously reported in Germany, Taylor,<sup>2</sup> in 1898, was the first American writer to treat the subject in a thorough manner. He collected all the cases that had been described earlier, which with his own made a total of 53; of these, 16 have detailed records. A striking feature of the disease is heredity, 35 of the 53 cases collected by Taylor having occurred in 3 families. It has been followed through five generations and is transmitted through both the male and female lines. The clinical manifestations occur in distinct paroxysms at irregular intervals between which the patient is apparently in perfect health. The attack most often comes on during the night, the patient waking in the morning with inability to move. The voluntary muscles are involved almost exclusively and in varying degrees. The paralyzed muscles are flaccid and do not respond to electric stimulation and the reflexes are lost. There is no impairment of the mental faculties and sensation remains normal. The duration of the attack is usually from six to seventy-two hours, after which time the paralysis gradually disappears and the reflexes and

electric excitability return. The paroxysms have usually first occurred at about puberty and have gradually disappeared between the ages of forty and fifty.

Since Taylor wrote upon the subject, cases have been reported in America by Mitchell<sup>3</sup> of Philadelphia, Putnam<sup>4</sup> of Boston, and Crafts<sup>5</sup> of Minneapolis. Various theories have been advanced to account for the symptoms. A toxic substance which causes the disease has not been proven to exist, although sought for in the urine and feces. Putnam advances the idea that "the symptoms are probably due to the morbid over-action of an influence which, though hitherto but little recognized, probably plays an important part in all the operations of our lives, and which has been designated as "inhibition." Meltzer<sup>6</sup> defines inhibition as a temporary diminution or abolition of a vital activity brought about by an external or internal stimulus. According to this theory all irritable tissues of the living body respond to a stimulus with a specific activity, as well as with an inhibition of this activity, the actual effect of a stimulus being always only a resultant of the two opposing factors. This theory still leaves the particular stimulus uncertain and it may be a toxic substance or something else. Family periodic paralysis, epilepsy and migraine are so similar in many of their characteristics that writers have repeatedly noted it. The hereditary tendency to the paroxysms is very marked in migraine and family periodic paralysis and, according to some, also in epilepsy.

In none have any abnormal anatomical changes in the nervous system been constantly found. The resemblance of the symptoms to those due to certain poisons has led to the construction of theories of intoxication, but nothing definite is known regarding the poisons supposed to operate in these cases. The explanation by means of imaginary "periodic discharges of nerve-force" or by "nerve storms" brings us no nearer to the conditions and activities provoking the storms. Since the members of this group of paroxysmal neuroses are so similar in many ways, a comparative study may be of value in helping to clear up some points in connection with each.

#### THE NATURE OF THE CELLS IN PIGMENTED MOLES.

Pigmented moles in various parts of the body not infrequently become the starting-point of melanotic tumors, often of exceedingly great malignancy and widespread metastasis. In 1871 Durante, in Italy, first advanced the view that the cells composing nevi are epithelial in origin and not mesodermal as held by Rokitsansky and Virchow, and upon this basis he brought forward a theory of the origin of tumors in a matrix of embryonal cells, a theory which Cohnheim proposed quite independently three years later. More recently Unna, ignorant at the time of Durante's views, strongly advocated the genesis of nevi in epithelium, and since then, especially

1. Brain, xxiv, 1901, 257.

2. Journal of Nervous and Mental Diseases, September and October, 1898, 637 and 719.

3. Amer. Jour. Med. Sciences, November, 1899, 513.

4. Ibid., February, 1900, 160.

5. Amer. Jour. Med. Sci., June, 1900, 651.

6. N. Y. Med. Journal, May 13-27, 1899.

recently, much has been written on both sides of this question. The followers of Durante and Unna refer to the melanotic tumors arising in moles as melano-carcinomata or as nevo-carcinomata, whereas others continue to speak of them as melano-sarcomata.

Recently, Abesser<sup>1</sup> in Orth's laboratory in Göttingen, and Larass,<sup>2</sup> working in Lubarsch's laboratory in Posen, have published the results of investigations concerning the origin and genetic significance of the cell masses in cutaneous nevi. Both reach conclusions positively in favor of Unna's views. They derive the round and oval nevus cells as well as the branching pigment cells from the epidermis from which they are separated by a peculiar transformation with softening and loss of the epithelial fibrillation. According to Abesser, the nevus cells at first may be connected with one another and with adjacent typical epithelial cells by fine protoplasmic bridges. The cells thus separated are not regarded as changed into connective tissue cells but as retaining their epithelial character, the process being regarded as a species of metaplasia. Later, connective tissue and elastic elements grow in among the cell heaps from the surrounding tissue. In spite of the convincingness of the appearances described by these investigators, especially Abesser, and regarded by them as fully demonstrating the origin of the nevus cells in the epidermis, the unquestionably sarcomatous behavior and general biology of the malignant tumors springing from nevi may be urged with considerable force as strongly suggesting that pigmented moles may take their origin from aberrant mesodermal cells misplaced into the lower layers of the epidermis whence they may break loose and again enter the cutis. In view of the fact that the malignant tumors arising in nevi clinically and anatomically resemble sarcoma rather than carcinoma, especially as we know it when arising in the epidermis, the peculiar morphologic appearances in moles should not be accepted as necessarily decisive. The problem is still worthy of further study, especially by means of serial sections of nevi in the newborn and at a time when they are in process of formation.

While the question whether the melanotic tumors arising in pigment moles are melano-carcinomata or melano-sarcomata may be regarded as a purely academic one of little or no real practical significance—the arguments for and against that way of looking at things need not be discussed now—the significance of moles as the starting-point of rapidly malignant and usually pigmented tumors can not be too strongly emphasized. The slightest sign of growth in a pigmented mole should lead to prompt and thorough removal. False conservatism in case of moles upon the face, for instance, and crude efforts at removal by means of strings and pastes have been followed more than once by rapid growth and fatal generalization. There lurks in the cells of pigmented moles a hidden potency for malignant growth that can not receive too much attention.

#### THE RELATION OF ARSENIC TO ALCOHOLIC NEURITIS AND BERI-BERI.

During the last half of 1900, there occurred in England a most remarkable epidemic of peripheral neuritis which was referred to at the time in *THE JOURNAL*.<sup>1</sup> The cases were limited to persons who drank beer and were first considered to be instances of alcoholic neuritis. The presence of certain symptoms not observed in the usual cases of peripheral neuritis due to alcohol, especially pigmentations and keratosis of the skin, running of the eyes and nose, pain, redness and swelling of the soles of the feet and often also of the palms of the hands, led Reynolds of Manchester to suspect that arsenic might be the cause of the disease. The beer of the district was submitted to chemical examination and found to contain arsenic, usually in considerable quantity. The source of the arsenic in the beer was traced to the sugars used in brewing. The sugars were prepared from cane sugar and starch by the action of sulphuric acid, which, when crude, often contains arsenic. After Reynold's extensive experience with these cases he is inclined to suspect that arsenic is a factor in the production of many cases which have passed as "alcoholic neuritis." In the arsenical cases, the poison is found in the urine, the hair and the skin. It is not unlikely that the combined action of alcohol and arsenic may, as has been suggested, be more liable to cause neuritis than either alone.

Some of those who observed the epidemic in England called attention to the marked resemblance between arsenical neuritis and beri-beri. So strong was the likeness that some medical men in Chester held to the diagnosis of beri-beri even after arsenic had been found in the beer consumed by the patients. The absence of skin lesions in cases of beri-beri is usually considered sufficient to differentiate them from those of arsenical neuritis. It is possible, however, that skin eruptions and pigmentation may have been overlooked in dark-skinned races. Some epidemics of beri-beri on shipboard and in institutions may have been instances of arsenical poisoning from contaminated food or drink. Some observations made by Ross in connection with beri-beri, while they do not show conclusively that arsenic is the essential cause of the disease, at least suggest such a possibility. In August, 1901, a patient came under the observation of Ross<sup>2</sup> in which there was a peripheral neuritis so similar to beri-beri and to arsenical neuritis that the diagnosis was reserved. The hair of the patient was found to contain a considerable quantity of arsenic. The source of the arsenic could not be traced to beer but it might have been contained in the canned food which the patient had eaten largely, either in glucose, in preservatives or in the tin lining of cans.

More recently Ross<sup>3</sup> reports the results of the chemical examination of hair from 21 cases of beri-beri, 20

1. *JOURNAL A. M. A.*, Dec. 15, 1900, 1587; Dec. 22, 1900, 1641; Jan. 26, 1901, 268; Feb. 9, 1901, 392.  
2. *British Medical Journal*, Oct. 5, 1901, 979.  
3. *Ibid.*, Feb. 8, 1902, 329.

1. *Virchow's Archiv*, 1901, clxvi, 40-66.

2. *Inaugural Dissertation*, Leipzig, 1901.

of which specimens came from Penang, a known beriberi locality. In 6 of the specimens of hair arsenic was found. Ross does not claim to have shown that arsenic is necessarily the cause of the disease but leaves the question open for the present. He notes that arsenic was found in recent cases and suggests that the distance from the scalp at which the hair was cut may influence the findings. It will be interesting to follow the results of further investigation in connection with these diseases, which are so nearly alike in most clinical peculiarities.

#### CREDULITY AND MEDICINE.

In his interesting address on "Belief and Credulity,"<sup>1</sup> Professor Jastrow of the University of Wisconsin has occasion to refer to credulity as applied to medical and kindred matters. Naturally, some of his most striking illustrations are from other fields than medicine, but in order to complete the collection of the types of credulity which he desires to illustrate he refers to Eddyism as a system of interpretation of facts which though "startling and contradictory to ordinary experience, gains widespread credence, and that in spite of pronounced inconsistency with verifiable observation and common sense." He then goes on to say:

"Even in this field of intellectual effort the land of the free and the home of the brave has contributed an article worthy to compete with the foreign product. Eagle-like, this system spreads its wings and soars free from the bonds of sense or earth-bound realities, free from human logic and the errors of mortal mind, free from the material impediments which the Author of Nature has inconsiderately set in our paths, free to make things so by thinking them so, free to set method and learning and experience at naught. And surely it calls for bravery of no common order to resist the seductive appeals of eye and ear, to sail steadily on heedless of the calls of the sirens of rationality, convinced at the outset that things can not be as they are. . . . It is not necessary in this connection to recount the beliefs of this system; it is sufficient to point out that when thousands of intelligent persons give practical adherence to, and enroll themselves under the banner of one who teaches that a bunion would be an adequate cause of insanity if only we held the same belief about the bunion as we do about congestion of the brain; that smallpox is contagious by reason of the same agencies as make weeping or yawning contagious; that fear may be reflected in the body as fractured bones, just as shame is seen rising to the cheek; that anatomy and physiology and hygiene are the husbandmen of sickness and disease, while the reading of a text-book of christian science is equally effective in producing health; or that when a healthy horse takes cold without his blanket, it is on account of the poor creature's knowledge of physiology—then such persons can hardly complain if they are cited as instances of modern credulity."

Professor Jastrow is well aware that this extreme instance of departure from rationality is not an isolated example of the boundless credulity of mankind in matters medical, and he refers to Oliver Wendell Holmes' "Homeopathy and Its Kindred Delusions," as an inter-

esting study of some of the various forms that this credulity has taken. The address is a stimulus to intellectual virtue and right belief, and it is especially valuable because the author calls attention so directly to credulousness as illustrated by subjects connected with medicine.

#### ENDOWMENT OF MEDICAL EDUCATION.

\* The enlargement and endowment of the Harvard Medical School seems like the opening of a new day in medical education. The gift of \$1,000,000 for new buildings by Mr. Pierpont Morgan was quickly followed by another from Mr. Rockefeller of a like sum conditional only upon the raising of about three-quarters of a million by the college from other sources. Now, this condition has been more than met by the contributions of the alumni and the donation by Mrs. Collis P. Huntington of \$250,000 for a pathological laboratory to be erected as a memorial of her late husband. A few more such benefactions judiciously distributed throughout the country will go far to furnish the opportunity, so far as material resources are concerned, to put this country well in the front in the advancement of medical science. Harvard will now be judged by her opportunities; if she fails to take the lead it will be to her discredit. A fortunate circumstance is that Mr. Rockefeller's donation is available for general endowment purposes instead of being specially for new buildings like the Morgan gift. Tying up funds in brick and mortar is sometimes a favorite practice of donors and trustees, but an absolute hindrance to the scientific usefulness of the gift. It is here as elsewhere "the man behind the gun" who wins, and endowment of medical research is more important than the mere housing of it, showy and effective as the latter may be in some ways. A building is a perpetual charge; an income-producing investment is the reverse and available for whatever needs may develop. We need endowment funds for our medical colleges all the more to free them from the commercial tendencies that have afflicted them in the past and still exist to a certain extent. A really high-class institution can not depend upon the income of the lecture fees. It is to be hoped that the better endowment of medical instruction now started in this country will soon have its effects in raising and maintaining the medical standards.

#### DISINFECTION AND HEALTH DEPARTMENTS.

In cities of considerable size we have learned to depend very largely upon the public department of health for the disinfection of houses after cases of contagious diseases. While this is often convenient and, in the case of people who are in very moderate circumstances, almost essential, it has some decidedly objectionable features. The men who do this work in health departments are usually appointed for other reasons than their special ability to do the required work. Many physicians have observed infection of healthy persons who have returned to houses which were supposed to have been disinfected by health department employes. The proper disinfection of a house after any of the contagious diseases requires the services of a conscientious man who possesses some technical training and a good deal of com-

1. Educational Review, January, 1902.

mon sense. To hang a sheet in a room and spray some formalin upon it is not thorough disinfection, although it may be as much as a department of health can afford to do. When people are able to pay for proper disinfection, it should be done in a most complete manner. In large cities there is work enough of this kind to furnish a profitable business for some well-qualified men who could be depended upon, and recommended, by the medical profession to families who request that their homes be disinfected. There is no more reason why a public department of health should furnish free disinfection of houses for people who can afford to have it done than that health department laboratories should make gratuitous examinations of blood for diagnostic purposes in cases where the patient could pay. There is a tendency to impose too much upon public health departments and to secure from them the performance of work which should be done by qualified private individuals who are properly paid for it.

#### THE FUTURE WOMAN.

In his "Descent of Man," Darwin suggested the probability that such natural weapons as horns and tusks, when present in both sexes of an animal species, were originally only possessed by the male and their possession by the female was a later acquirement; in other words, the female gradually usurped the offensive and defensive appendages of the male. Darwin's inference has lacked paleontologic proof until lately. In a recent paper,<sup>1</sup> Dr. C. I. Forsyth-Major has taken up the question from this point of view, considers the evolution as shown in fossil remains of the deer, giraffe, bovine and porcine families—all possessing these appendages—and comes to the conclusion that Darwin was about right. The subjection of the female, so far as it was dependent upon her not bearing arms according to the fashion of her kind, therefore came largely to an end. Major applies this fact to our own species, and concludes his paper, as quoted by *Science*, with the following: "In our own species the modern aspirations of women are to all appearances incipient signs of the same natural law. Physical and mental character of man, originally acquired in the struggle of the males, are apparently being slowly transferred to women. They only require time for their full evolution." We can now see what we are coming to; the new woman is all right in the natural order of things and has bovine and cervine, etc., precedents in her favor. In a few more geological periods the descent of man from his pinnacle of physical superiority may be complete. Perhaps it may be some comfort to appreciate the fact that when the paleontologic evidence is being looked up in the case of man and when the female Jeffries and Fitzsimmons are holding the belt, those of us who now object to the coming order will be out of the ring and fossils in dead earnest.

1. *Geological Magazine*, December 4, vol. viii, 1901, referred to in *Science*, Feb. 28, 1902.

**Turpentine in Infectious Diseases.**—M. Nasaroff observed very favorable results from the administration of turpentine in 70 cases of erysipelas, 18 of parotitis, 6 of scarlet fever, smallpox and suppurating affections of the uterus. He gave fifteen drops in milk two or three times a day.—*Voenno-Med. Journal*, September, 1901.

## Medical News.

### CALIFORNIA.

**New Hospital for San Diego.**—The supervisors of San Diego County have passed a resolution to proceed with the preliminaries for the erection of a county hospital on a lot owned by the county on University Heights, San Diego.

**Chico Physicians Revolt.**—The municipal license imposed on physicians at Chico is causing trouble. The physicians of the city, instead of meekly turning over \$5 to the city marshal on his quarterly visits, have made up a purse and propose to resist the collection of what they consider an unjust tax.

**Lane Memorial.**—Memorial services for the late Dr. Levi Cooper Lane, of San Francisco, were held in Lane Hall, Cooper Medical College, March 9. Dr. Henry Gibbons, Jr., presided and presented the tribute from the trustees; W. D. Blake, of the class of 1902, spoke for the undergraduates; Dr. Charles N. Ellinwood, on behalf of the faculty, alluded to the sense of great personal loss felt by Dr. Lane's associates; and Dr. Edward R. Taylor, vice-president of the college, spoke of the courage with which Dr. Lane faced and overcame difficulties in the mastery of his profession.

### DISTRICT OF COLUMBIA.

**Few Applicants for Medical Military Glory.**—On April 7, the examination of applicants to fill 64 vacancies in the army medical department will be begun. Only 54 applications for examination have been received.

**Dr. Godding's Portrait.**—A handsome oil painting of the late Dr. William W. Godding, for twenty years superintendent of the Government Hospital for the Insane, has been finished and will be hung in the assembly hall of the administration building of the institution.

**The Columbian University** has just completed plans and let contracts for the erection of a new hospital building and a new medical and dental school on H Street, N. W., between 13th and 14th. The buildings will be colonial in style. The hospital has a frontage of 60 feet, and the medical school building, 50 by 144 feet, will be five stories high.

### ILLINOIS.

**For Million's Money.**—Suit has been entered in the Circuit Court of Sangamon County to set aside the will of the late Dr. John L. Million, whose estate exceeded \$100,000 in value. The estate was left in trust for the benefit of the widow and her two sons. It is claimed that Dr. Million's mind had become affected from the use of strong medicines and narcotics before the testament was drawn.

### Chicago.

**An Accredited College.**—The Royal College of Physicians of London and Royal College of Surgeons have placed on their limited list of accredited colleges, the Northwestern University Medical School (Chicago Medical College).

**Smallpox Among Negroes.**—The Commissioner of Health reports that with only 1.75 per cent. of the total population of the city, the colored contingent has furnished nearly 80 per cent. of the last group of smallpox cases. Between March 4 and March 22 there were 34 cases discovered, 7 white and 27 colored.

**The City's Mortality.**—During the week ended March 22, 537 deaths occurred, a reduction of 17 deaths from those of the previous week, but an increase of 72 as compared with the corresponding week of 1901. The death-rate per 1000 per annum was 15.38. The principal causes of death were: Pneumonia, 88; consumption, 59; heart diseases, 52, and bronchitis, 34.

**X-Ray Diagnosis.**—The autopsy on the late Dr. Christian Fenger confirmed a diagnosis made by a skiagraph last fall. At that time Dr. Fenger had an attack of colic, which he thought might be due to gallstones, and a skiagraph taken by W. C. Fuchs showed small dark shadows in the region of the gall-bladder. At the autopsy, three gallstones were found in the viscous.

**"Pink Eye" is Influenza.**—The so-called "pink eye" which has been increasing in prevalence for some weeks is only another manifestation of the grip or influenza bacillus. The Department of Health advises that every case of "pink eye" be at once subjected to a bacteriologic examination for the influenza bacillus; if this be found in the secretions the indication for treatment is obvious, and a cure may be effected within forty-eight hours. These examinations are made in the laboratory

for physicians without charge and the results are telephoned without delay.

#### IOWA.

**To Regulate Barbers, Osteopaths and Opticians.**—Three new state boards are contemplated in pending bills—to control and regulate barbering, osteopathy and optometry. The bill for a board to issue certificates to osteopaths provides that they shall receive certificates, not as medical practitioners, but as osteopaths.

**Waterloo Emergency Hospital.**—Drs. Daniel W. Crouse, Reuben A. Dunkelberg, Thomas U. McManus, William B. Small, Lafayette W. Case, Elmer E. Dunkelberg, Henry W. Brown, Fred W. Keehl, have incorporated the Waterloo Emergency Hospital Association with a capital stock of \$20,000.

**Dr. Hill Resigns.**—Dr. Gershom B. Hill, who has been superintendent of the Iowa Hospital for the Insane, Independence, since 1881, and who, for seven years prior to that time, was assistant physician in the institution, has notified the Board of Control of State Institutions that he will not be a candidate for re-election. He expects to locate in Des Moines and to practice medicine as a specialist in insanity.

**Reciprocity.**—The bill introduced by Dr. Emmert, of Atlantic, for granting of certificates to practice medicine and surgery in the State of Iowa without examination has been up in regular order and passed. It grants a certificate to practice medicine and surgery in the state without an examination where a certificate can be shown that such permission has been given in other states; that is, where the applicant comes from a state which grants a like favor.

#### KENTUCKY.

**Cornerstone Laid.**—The cornerstone of the new \$80,000 German Deaconess Home and Hospital, Covington, was laid, March 16, with appropriate ceremonies.

**Alumni Meeting.**—Beginning March 25 and continuing for two days, the Alumni Association of the Louisville Medical College held its annual meeting. The arrangements were in charge of Drs. A. O. Pfingst, Aug. Schachner and Irvin Abell of the faculty of the college. Among the out-of-town members in attendance were Drs. J. A. Burroughs, of Asheville, N. C.; R. C. McChord, Lebanon; Arch Dixon, Henderson, and J. A. Harris, of New Albany, Ind. Dr. J. W. Fowler acted as toastmaster at the annual banquet at the Galt House.

**Stringent Vaccination Order.**—The Bowling Green Board of Health has issued an order requiring all persons who have not been vaccinated within three years to submit to vaccination within five days. Each person, man, woman and child, must be vaccinated at three places, on the arm or body, and shall be revaccinated until the operation is successful. The alleged smallpox patients have been removed to the pesthouse. City Health Officer T. B. Wright has been instructed to visit the schools and see that the order of the board is complied with.

**Recent Legislation.**—The governor has signed two bills of interest to the profession, which were passed by the late legislature. One is an act to regulate the practice of barbering, the registering and licensing of persons to carry on such practice, to insure the better education of such practitioners, to insure better sanitary precautions in barber shops and to prevent the spread of disease in the state of Kentucky. The other bill is an act to establish and maintain free public libraries in cities of the first class; this enables Louisville to avail itself of the offer of Carnegie of \$250,000 for a building to be used for library purposes. The profession is a unit in its endeavor to have the mayor appoint a member of the medical profession one of the twelve trustees of the library in order to establish a good medical library as one of its departments.

#### MARYLAND.

**Art Loan Exhibit for Hospital.**—An art loan exhibit was held for the benefit of the Frederick City Hospital Association.

**Baltimore Mortality.**—The death rate continues low, only 188 deaths being reported in the week ended March 22, against 245 for the same week last year. Of the causes of death consumption claimed 21, pneumonia 16, and cancer 7.

**New Hospital at Annapolis.**—As a result of the recent visit of the Surgeon General of the Navy, the old naval hospital on the government farm at Annapolis is to be remodeled and made into a hospital for mariners and sailors. The building originally cost, with land, \$200,000, and was erected when Admiral Porter was Superintendent of the Naval Academy. It has been long in disuse and used as a storage warehouse. It is

built in the shape of an anchor, and has a frontage of 260 feet. It is charmingly situated with a beautiful view of the bay, Annapolis City and the surrounding country, and the situation is very healthful.

**Personal.**—Dr. George French Owens, a physician of Upper Marlboro, Prince George's County, has received an appointment as assistant surgeon, U. S. Army, and has been ordered to the Philippines. He is a graduate of the University of Maryland. —Drs. Bernard A. Goodman and W. A. Davis, Baltimore, have resigned positions as health warden and have been succeeded by Dr. Thomas Sudler. —Dr. H. J. Berkley had his eyeball removed, March 16, for an injury received from a piece of steel flying into his eye while working on an instrument. Two other members of the Johns Hopkins Medical School have each lost an eye previously, namely, Dr. J. J. Abell, from an explosion in his pharmacological laboratory, and Dr. Miller, from infection while operating on a pus tube.

#### MISSOURI.

**St. Louis Not Responsible.**—Circuit Judge Fisher decided, March 17, that the city was not responsible for damages in the death of the thirteen children who died some time ago from tetanus caused by the administering of antitoxin procured from the Board of Health.

**The Gregory Banquet.**—Cards are out announcing that the St. Louis Medical Society will give a testimonial banquet to Elisha Hall Gregory, M.D., LL.D., to commemorate his fiftieth anniversary as a teacher of medicine. It will be held at the Planters' Hotel, St. Louis, April 17.

**Change of Asylum Control.**—On March 12, the change of management in State Insane Asylum No. 1, Fulton, became operative. Dr. James W. Smith, Pleasant Hill, assumed his duties as superintendent, with Drs. Zachary T. Martin, William M. Bayliss, and J. Frank Harris, assistants.

**Ensworth College Commencement.**—A class of 14 was graduated from Ensworth Medical College, St. Joseph, March 17. Dr. P. I. Leonard presided as master of ceremonies; the faculty address was by Dr. Charles G. Geiger. An address was delivered by Dr. William G. Moore, St. Louis, and the degrees were conferred by Dr. T. H. Doyle.

#### NEBRASKA.

**Medics vs. Dents.**—For two hours on March 20 a fierce fight was waged at Omaha between 300 medical and dental students. More than 100 were injured, two seriously.

**License Revoked.**—The State Board of Health has revoked the license given to Dr. E. B. Oliver in August last, on the ground that he was an itinerant physician and that some of his practices were unprofessional.

**Methodist Hospital at Omaha.**—The lay press announces that work will be commenced on a Methodist Hospital at Omaha, 432 by 250 feet, and with accommodations for 150 patients. The hospital is to cost \$225,000.

**The Smallpox Situation.**—A correspondent summarizes the smallpox situation in the state and the deficiencies of state laws regarding sanitation. During the winter of 1901-2, there were more than a thousand cases of smallpox in Omaha and South Omaha; 250 cases were present at one time in the two cities. These cities, Lincoln and the Indian agencies have suffered greatly. South Omaha has been particularly negligent with reference to the matter for the reason that the cases were mild. Omaha has been honored with a visit from the representative of the United States Marine-Hospital Service, Dr. C. P. Wertenbaker. To its shame be it said the State of Nebraska has absolutely no laws with reference to any duties or any powers of the State Board of Health from a sanitary standpoint. Their only duties, as prescribed by law, are as a license-granting body. Past legislatures have uniformly been niggardly and have never thought it necessary to furnish means in the direction of human sanitation, although they have given generously for hog sanitation. This year the Board has a small sum and, in spite of absence of law, is using it in the proper manner. The situation has been so bad throughout the state that Dr. Wertenbaker has been sent here. In order to become most thoroughly acquainted with the real situation, he became, for the time, an aide to the governor.

#### NEW YORK.

**Oswego Hospital.**—It is announced that \$12,000 has already been subscribed for the new hospital at Oswego.

**M. W. Townsend Operating Room.**—The Genesee County Medical Association, at its meeting in memory of Dr. M. W.

Townsend, deceased, requested the directors of the Batavia Hospital Association to name the operating room at that institution the M. W. Townsend Operating Room.

**Hospital Bill a Law.**—The Governor has signed the Hartford hospital bill which provides that in counties that do not contain a hospital, and that adjoin counties of another state that do contain hospitals, contracts may be made between the municipality in the one county and the hospital authorities in the other for hospital treatment, etc. The bill further legalizes the acts of village boards in appropriating moneys for said purpose in the past and provides that they must be paid.

**Commission on Prophylaxis.**—A bill has been introduced into the assembly providing for a commissioner to inquire into the history, nature and pathology of vaccination, the history, nature and pathology of smallpox from the time of Sydenham to the present time; the value of vaccination as a prophylactic against smallpox; the history, nature and pathology of antitoxin and other serums alleged to be prophylactic against diphtheria, hydrophobia, phthisis and other diseases; whether there is any danger of the bubonic plague or other severe epidemics visiting the United States and the State of New York, and if so, what measures should be taken to avert any and what alteration in regard to the matters above mentioned should be made in the existing law. The commission is to be called the Commission on Prophylaxis, and will consist of five members appointed by the governor.

#### New York City.

**Personal.**—The President of the United States of Venezuela has conferred the high class "Decoration of the Bust of the Liberator Bolivar" on Dr. Emil Henel. Dr. Gustavo Tosti, vice-consul of Italy, was graduated from Long Island College Hospital in 1901 and passed the state examination last month.

**Hospital in Statu Quo.**—The Board of Directors of the Memorial Hospital for Women and Children, Brooklyn, has voted by a large majority to continue the hospital on the plans on which it was organized; to maintain it as a hospital for the treatment and care of women and children, and has accepted the resignation of Mrs. John H. Burtis, who had been president for many years.

**Skene Memorial Window.**—In the new St. Paul's Protestant Episcopal Church, Flatbush, there has been placed a beautiful art window to the memory of the late Dr. Alexander J. C. Skene. The window was designed by Julius Hausleiter. It has been placed directly over the altar, occupying a space 14 by 19 feet. The subject is "The Great Physician." Beneath is the sentence, "Come unto Me all ye that labor and are heavy laden and I will give you rest." In a separate panel is this inscription: "To the Glory of God and in Loving Memory of Alex. J. C. Skene, M.D., LL.D."

**Staten Island Physician Censured.**—The Health Board has censured a Staten Island physician for failure to report a case of smallpox which came to his attention last January, and with the announcement of this official action it was intimated that the names of two, and possibly three, other physicians who are under suspicion for the same dereliction of duty would also be published. The failure on the part of doctors to report cases is due either to carelessness or a desire to show some special favor to a patient—more frequently the latter. A doctor has no right to exercise discretion in these questions of the public welfare.

**Want Ward's Island as It Was.**—At a largely-attended meeting of the New York County Medical Association, March 17, the following resolutions were unanimously passed:

To His Excellency the Governor of New York:

WHEREAS, Lunacy Bill No. 368, recently passed by the Legislature, has abolished the positions of the two medical superintendents at Ward's Island, New York, it has placed two officers under one head, thus putting over four thousand insane patients under one management; and

WHEREAS, The supplemental bill amending Bill No. 368 is now before the Legislature, restoring these positions, so that the divisions of the hospital as they formerly existed—one for men and one for women—may be maintained.

Resolved, That the New York County Medical Association heartily indorses this amendment and advocates its immediate passage.

On March 20, the New York Academy of Medicine unanimously adopted the following resolutions, which were presented by Dr. J. D. Bryant:

WHEREAS, Lunacy Bill No. 368, recently passed by the Legislature, places about 4000 insane patients of Ward's Island under the medical supervision of a single superintendent, and

WHEREAS, In the opinion of the New York Academy of Medicine the magnitude of such a burden as that is far too great to be wisely and safely borne by a single head, be it therefore

Resolved, That the Fellows of the New York Academy of Medicine do hereby respectfully register their objection to such a course

of action, and earnestly petition his honor, the Governor of the State, that not less than two superintendents be placed in charge of said patients.

Resolved, That a copy of this resolution be forwarded by the Secretary of the Academy to the Governor at Albany.

#### NORTH CAROLINA.

**Medical College to Open.**—The Medical Department of the North Carolina University at Raleigh will open in September. Medical students who have taken the first two years' studies at the university will be able to graduate after two years' study in the medical college, according to press notices.

**Attempted Poisoning.**—The entire family of Dr. David T. Tayloe, Washington, president of the State Medical Society, was poisoned, March 17, by arsenic. Prompt medical care averted serious results. Dr. Tayloe's negro driver was arrested on the charge of attempted poisoning, was taken from jail and lynched by "parties unknown."

**Aldermen Approve College.**—The board of aldermen of Raleigh has adopted the following resolutions providing for a free dispensary for medical students:

WHEREAS, The college can not succeed without proper medical facilities and hospital managements, therefore be it

Resolved, By the board of aldermen of the City of Raleigh that a free dispensary be established at the Box Hospital building, where the city physician be required to attend outdoor charity patients of the city instead of as at present in his own office.

Resolved, That the students of the University of North Carolina Medical College be allowed the privilege of visiting the dispensary and of being instructed in the methods of examining patients under the supervision of the city physician.

#### OHIO.

**Memorial to Dr. Emily Hill.**—The Wood County Medical Association, at its recent meeting at Bowling Green, passed resolutions in memory of Dr. Emily Hill, the only woman in the association, who died, February 7.

**Cocain Bill Passed.**—The House has passed the bill prohibiting the sale of cocain except on the prescription of a physician. It is to be labeled "poison," and the names of the purchaser and the person for whom it is purchased are to be recorded by the selling druggist.

**For the Care of Indigent Crippled Children.**—A bill looking toward the state providing for indigent, crippled and deformed children has been introduced before the legislature by Senator Warner, of Cuyahoga. It provides for the appointment by the governor of a board of five to serve without compensation. This board shall have the power to contract with hospitals, institutions or organized bodies for the care and treatment of indigent, crippled or deformed children, or those suffering from disease likely to result in deformity. The bill carries an appropriation of \$10,000 for each of the next two years to defray the expenses for such care of this class of children.

**A Non-Compromising Compromise.**—A so-called compromise has been effected between the State Medical Board, representing the physicians of the state, and the osteopaths. The latter will not insist upon a separate board for the examination of the candidates for the practice of osteopathy, but, instead, an amendment to the present state medical law has been agreed upon by which the State Medical Board will appoint three osteopaths to examine applicants for degrees in that school. The examination will be in the principles and practice of osteopathy. The State Board of Medical Examination and Registration will examine all candidates recommended by the osteopathic committee of three in anatomy, physiology, chemistry, and physical diagnosis, as provided by the present statute. This so-called compromise is really a complete victory for the physicians of the state.

#### PENNSYLVANIA.

##### Philadelphia.

**Bequests.**—The following bequests have recently been announced: Justice B. Crandall, Ocean View, N. J., to the Women's Hospital, Philadelphia, \$5000; Benjamin Brooke, to the House of Refuge, \$10,000, the income to be devoted to Christmas dinners, etc.

**Polyclinic Change.**—Dr. J. Alison Scott has been elected professor of clinical medicine and therapeutics at the Philadelphia Polyclinic to fill the chair recently resigned by Dr. Solomon Solis-Cohen. Dr. Scott is instructor in clinical medicine at the University of Pennsylvania and physician to the Pennsylvania Hospital.

**Bazaars for Hospitals.**—The board of managers of Jefferson Maternity Hospital lately held a bazaar, which netted about \$1000 for the institution. A similar function was recently given for a fund to build a sun-parlor for the medical

ward of the University of Pennsylvania, as a result of which about the same amount was realized.

**Decrease in Typhoid and Smallpox.**—New cases of both typhoid fever and smallpox show a marked decrease. Of the latter there were only 35 new cases for the week ended March 22, as against 53 for the previous week; 219 cases are still under treatment at the Municipal Hospital. The sum of \$225,000 has been appropriated by councils for expenses incurred in the suppression of the smallpox epidemic. It is estimated that more than \$80,000 will be required to pay the vaccine physicians.

**The New Jefferson Hospital.**—The proposed new Jefferson Medical College Hospital is soon to be under way. Plans and specifications have been accepted. An appropriation of \$50,000 was made by the last Pennsylvania legislature for the enterprise, on condition that the work on the building should be begun not later than June 1. It is assured that the condition will be fulfilled. Hon. William Potter, chairman of the Board of Trustees, has recently donated \$50,000, to which is added a bequest of \$65,000 from the J. Alfred Kay estate.

#### GENERAL.

**Cholera in Manila.**—On March 22, there were reported at Manila, P. I., 16 cases of cholera and 15 deaths; March 23, there were 5 additional cases and 5 deaths reported. On March 24, up to noon, there had been a total of 26 cases and 21 deaths; at noon of the 25th there were 49 cases and 39 deaths.

**Mortality Rate of Manila.**—In its population of 250,000, Manila had, during the month of December, 858 deaths and 406 births. The annual death rate per 1000 was 40.43; this high rate was due to the Filipino mortality, 51.42 per 1000. The rate among the American and European whites was only 13.96 per 1000. The greatest mortality during the month was from infantile convulsions, which amounted to 255. The maximum temperature was 85; minimum, 68.6, and mean, 70 F.

**Vaccination Against Plague in Manila.**—The Manila Health Department is vaccinating, with the Shiga serum, all the Filipinos and Chinos of the city and such whites as desire it. The first large batch (200) was inoculated February 14, and it is expected that 100,000 will be so treated within the subsequent three months. Not a case of bubonic plague had occurred during the year up to leaving of the last mail, February 20. In the preparation of the smallpox virus eleven young water buffaloes are used.

**Health of Havana.**—As Major W. C. Gorgas, chief sanitary officer for Havana, will give way to a Cuban official on May 20, he sums up the work of the American health authorities in the following interesting statement:

The Army took charge of the Health Department of Havana when deaths were occurring at the rate of 21,252 per year. It gives it up with deaths occurring at the rate of 5720 per year. It took charge with smallpox endemic for years. It gives it up with not a single case having occurred in the city for over eighteen months. It took charge with yellow fever endemic for two centuries, the relentless foe of every foreigner who came within Havana's borders—which he could not escape, and from whose attack he well knew that every fourth man must die. It found Havana feared as a thing unclean by all her neighbors of the United States, and quarantined against as too dangerous to touch, or even to come near anything that she had touched, to the untold financial loss of both Havana and the United States. It leaves, after careful study of the question of yellow fever by its officers, undeterred by personal risk—for several of the investigators have died of the disease, contracted at their work. It has established the fact that yellow fever is only transmitted by a certain species of mosquito, a discovery that in its power for saving human life, is only excelled by Jenner's great discovery, and as time goes on, it will stand in the same class as that great boon to mankind.

**Medals of Honor.**—During the operations of our Army in Cuba, the Philippines and China, the commanders in the field reported numerous incidents of individual and unusual bravery, in recognition of which they recommended that medals of honor be given. Gen. MacArthur was president of a board of Army officers appointed to review the large number of recommendations received and to report these cases most deserving of recognition. On the report of this board 33 medals of honor have been awarded, 10 to officers, and 23 to enlisted men. Among the officers receiving these medals is Lieut. George W. Mathews, Assistant Surgeon, U. S. Army, formerly captain and assistant surgeon, 36th Volunteer Infantry, for most distinguished gallantry in action near Labao, Luzon, P. I., Oct. 29, 1899, in attending wounded under a severe fire of the enemy and seizing a carbine and beating off an attack upon wounded officers and men under his charge. The *Army and Navy Register*, in commenting on this, says:

It is an interesting fact recalled by the awarding of a medal of honor to Lieut. George W. Mathews, of the medical department,

that 5 of the 110 medals which are now held by Army officers were conferred upon officers of the medical department. This is rather surprising when it is reflected that medical officers are non-combatants and are not usually found on the firing line. Their position is supposed to be where there is difficulty for an officer to distinguish himself by the sort of valor which gains a medal of honor. The list of medical officers who win that distinction is steadily growing year by year.

#### CANADA.

**Canadian Medical Association.**—This Association will hold its annual meeting this year in Montreal on September 16, 17 and 18, under the presidency of Dr. Francis J. Shepherd of that city, Dr. George Elliott of Toronto being the general secretary. Professor Osler will deliver the address in medicine and Dr. John Stewart of Halifax, N. S., the address in surgery.

**The Southern Medical Association of Manitoba.**—This Association met at Brandon on February 26, nearly sixty physicians of the province being present. The following officers were elected; President, Dr. L. M. More, Brandon; secretary, Dr. Little, Alexander; executive council, Dr. Poole, of Neepawa, Dr. Goodwin of Elkhorn, Dr. Thompson of Douglas, and Drs. Macdonald and McDiarmid of Brandon.

**Ontario Medical Association.**—The next annual meeting of the Ontario Medical Association will be held in Toronto on June 4 and 5, under the presidency of Dr. N. A. Powell, of that city, Dr. Harold C. Parsons being the general secretary. Dr. J. T. Fotheringham has been appointed by the president as chairman of the Committee on Papers and Business. It is understood that the program will present several new and interesting features.

**Blackmailer Pleads Guilty.**—The attempt to extort \$200 from two Toronto practitioners by means of threats on the part of a man who had summoned both physicians to attend his wife and child respectively, did not work out as smoothly as the would-be blackmailer anticipated. After putting up a rather poor defense in the Sessions, the case finally terminated rather suddenly by the offender pleading guilty to the charge. Sentence will be pronounced during the week.

**Combined Arts and Medical Course at Toronto University.**—The Senate of Toronto University has recently passed a statute under the terms of which it will be possible hereafter for a candidate to secure the degree of B.A. at the end of his fourth year and M.B. at the end of his sixth year. Anatomy will be an optional study in the third and fourth years; and in this way a student at the end of his fourth year in arts will be enabled to proceed directly to his third year in medicine.

**Dr. Roddick's Bill Before the Special Committee.**—On March 20 the select committee appointed by the House of Commons to consider the terms of Dr. Roddick's bill to provide for a Dominion Medical Council, discussed the measure. Owing to the bill being considered in some quarters to infringe on provincial autonomy, Dr. Roddick explained that this law could not come into force in any province until said province had passed legislation putting it in force. The committee is to further consider the measure the present week.

**Personal.**—Dr. Harvey McKnight, Trinity, 1897, is visiting at his home in Toronto.—Dr. Richard Carney has been appointed city physician to Windsor, Ont., while Dr. J. A. Ashbaugh has been appointed medical health officer of the same place.—Dr. Harry J. Watson, Trinity Medical College, 1896, has been with the American Army in the Philippines for the past year. His superior officers have recommended him for distinguished service in the presence of the enemy. Dr. Watson practiced previously at Ottumwa, Iowa.

**Obituaries.**—Dr. A. Dixon Wagner died at Cornwall on February 13 at the age of 53 years. He was a graduate of McGill University.—Dr. Theodule Boldue, ex-house surgeon of the Notre Dame Hospital, Montreal, and who had just commenced practice in that city, died suddenly from heart disease on the afternoon of March 20, aged 26.—Dr. F. H. Thompson, of Seattle, Wash., died recently of typhoid fever. He was a son of a prominent citizen of Toronto and a graduate of Trinity Medical College. He was one of the officers of the coast and geodetic survey steamer *Patterson*, and had spent the last two years in Alaska, in the parts adjacent to Cape Nome and Sitka.

#### FOREIGN.

**Death of Medical Explorer.**—The African explorer, Dr. Emil Holub, died recently in his 56th year from malaria.

**Cholera Among Pilgrims.**—It is officially stated that over 1100 deaths have occurred this month in Mecca and Medina in Arabia.

**The second meeting of the International Conference for the Prophylaxis of Syphilis and the Venereal Diseases** will be held in Brussels, Belgium, Sept. 15 to 20, 1902.

**Compulsory Vaccination in France.**—A new law has been passed in France requiring vaccination against smallpox compulsory in the first year of a child's life, revaccination at 11, and again ten years later.

**Prizes for Future International Medical Congresses.**—After paying all the expenses of the last international medical congress, a surplus of about 40,000 francs is left. The committee expect to apply this sum as an endowment of a triennial prize to be awarded at future congresses.

**Prussian Appropriations for Medical Research.**—The Prussian government appropriates, for the present year, 53,000 marks for a cancer laboratory and ward, 10,000 marks to the committee on cancer research, and 20,000 marks for the study of means of prevention and early diagnosis of typhoid fever.

**Title for Soxhlet.**—The Bavarian crown has conferred a title of nobility on Prof. Franz Soxhlet, of the technical school at Munich and director of the agricultural experimental station. He is now chevalier of the Order of Merit of the Bavarian Crown, in token of appreciation of his contributions to milk hygiene, etc.

**Foreign Physicians in Brazil.**—Consul Kenneday writes from Para, Brazil, that a statute in that country provides that all physicians and dentists of foreign extraction who desire to practice their profession in any part of the country must first pass an examination at the medical colleges of Bahia and Rio de Janeiro. The law is to be more rigidly enforced in the future.

**Death of Kaposi.**—Vienna has lost the professor of dermatology and syphilis, Moritz Kaposi, who died the 6th inst. His name is familiar to physicians the world around. He was in his 65th year and had long suffered from a cardiac affection entailing distressing attacks of asthma, in one of which he succumbed. The twenty-fifth anniversary of his professorship was celebrated two years ago by an ovation from his numerous pupils and friends.

**XIVth International Medical Congress.**—The 14th International Congress of Medicine will take place at Madrid, Spain, April 23 to 30, 1903. The work will be divided among 16 sections. Intending essayists should send their articles, accompanied by a short résumé, before Jan. 1, 1903. Articles arriving after that date must be presented after the discussion on the subject has taken place. The official languages of the Congress in all the *séances* will be Spanish, French, English and German. In order to facilitate the work and meet the expenses, a special circular states, physicians who desire to inscribe their names should do so immediately, at the same time sending 30 pesetas (23 to 25 francs) to the secretary-general, Dr. Angel Fernandez-Caro, Madrid, who will send the necessary blank forms for presentation of communications and inscription.

**Suit for Damages Against Duehrssen.**—Prof. A. Duehrssen found it necessary to remove the uterus as the last resort in operating on a woman almost 45 years old, who had been referred to him by her physician for the relief of sterility. She had suffered from abdominal disturbances for some time and gave her age as 42. He found the rectum adherent to the uterus, and in detaching the adhesions serious hemorrhage followed, which he tried in vain to control by suturing the uterus and ligating the vessels. The discovery of a suspicious tumor supplemented the hemorrhage in indicating extirpation of the organ. An intestinal fistula developed later and the patient sued him for unnecessarily removing the uterus and the consecutive fistula. Most of the experts agreed that he should have consulted with the patient beforehand and obtained her consent to the operation. The "Staat-anwalt" fixed the amount of damages as 300 marks, but the judge acquitted the plaintiff, on the grounds that the patient's assertions had been contradictory in one or two points; that the fact that she had been referred to him by her physician constituted consent to an operation on her part, and further that there could be no question of malpractice as Duehrssen is the acknowledged authority in such cases.

#### LONDON LETTER.

**Extraordinary Action Against a Physician by a Patient for Induction of the Morphin Habit.**

The perils of medical practice and the fact that doctors in the discharge of their duty are liable to be the victims of un-

founded and vexatious actions is well known in this country. But seldom has such a flagrant example been furnished as the following: A nurse, the proprietor of a nursing home, brought an action against a London practitioner, Dr. Law, for damages on the alleged grounds that he had administered morphin, cocaine and other drugs to her, given her opportunities of administering the drugs to herself "to such an extent that she lost her reason and very nearly her life." It appeared that she suffered from spasmodic asthma, for which the doctor administered morphin hypodermically when other remedies failed, and that she acquired a taste for the drug and indulged in it to her detriment, and became a morphinomaniac. For the defense it was shown that the morphin treatment was adopted after consultation with Dr. Mitchell Bruce and other eminent physicians; Sir Douglas Powell and Dr. Theodore Williams bore witness that the treatment was correct. It was also proved that only the pharmacopoeial dose of morphia had been given by the doctor. On hearing the latter evidence the jury stopped the case and brought in a verdict in his favor, adding that the case should never have been brought into court. The judge fully concurred in the verdict and expressed his indignation at those who had advised plaintiff's counsel. It has been observed by an eminent judge that nurses' knowledge of medicine induces them to bring actions against physicians. Another example of this fact was given not very long ago. Dr. Cullingworth, the well-known gynecologist, performed ovariectomy on a nurse who afterwards brought an action against him on the grounds that she had not given her consent to such a radical operation. It was clearly shown that she had given permission to him to do what he thought necessary and that the operation was requisite. She lost her case, but for a long time persecuted the Doctor by raising all sorts of legal points and endeavoring to obtain a new trial. In recognition of the hardship a subscription list was opened to defray his legal expenses and the profession subscribed a large sum.

#### The Smallpox Epidemic in London.

The epidemic still continues to progress. On March 1, there were 1309 cases in hospital against 1102, 1185 and 1321 at the end of the preceding three weeks; 379 new cases were admitted during the week against 287, 390 and 502 in the three preceding weeks. Cases of failure to diagnose the disease continue to occur with consequent dissemination. Thus the medical officer of health for Stepney reports that on investigating an outbreak in a family he learned that the father had been unwell three weeks previously and had been treated for a fortnight by a doctor who diagnosed influenza. At the time of the medical officer's visit the patient had returned to his employment of dairyman. Five other cases subsequently occurred in the house.

#### The Midwife Bill. Second Reading Carried.

The bill to regulate the practice of midwives which was "talked out" in the House of Commons last year has passed its second reading in spite of considerable professional opposition. As has been explained in THE JOURNAL it is proposed to register midwives who alone will be allowed to call themselves such and to attend women in labor for gain. In order to be registered a woman must undergo a course of training and pass an examination. At present any woman, however ignorant and dirty, can call herself a midwife and attend cases of labor and carry puerperal fever from case to case. This is the only country in Europe in which the practice of midwives is not regulated. But since 1878 attempts have been made to legislate on the subject. The bill has been supported by the Royal College of Physicians, the Obstetrical Society and General Medical Council; but it is strongly opposed by the rank and file (by 95 per cent. it is estimated) and by the medical press. The reasons given are that the bill creates a "new order of practitioners" who can in the course of their short training acquire only a very rudimentary knowledge of midwifery and in whom recognition by the state will cause the public to impose unfounded confidence. Thus it is maintained that the bill is fraught with danger to the puerperal woman. The answer to this is that about two-thirds of the labors in the country are attended by midwives, usually because the patients can not pay for the services of a physician. The question is not one of a well-trained doctor or an imperfectly-trained midwife but of a midwife who has received some training or one who has received none.

#### Port Sanitation—Great Destruction of Rats.

Dr. Williams, medical health officer for the port of London, states that from Nov. 24 to Dec. 31, 1901, 2917 vessels were inspected. Six cases of plague were reported and 13 cases of typhoid fever dealt with. The war of extermination against

rats continues to be vigorously carried out, 10,164 having been destroyed since the last report. In a subsequent report for the month of January, 1902, it is stated that 7626 rats have been destroyed, bringing the total up to 100,000. In one large steamer no fewer than 1000 rats were found after fumigation.

#### Losses in the South African War.

An official statement just issued shows that the casualties from the beginning of the war to the end of February were 89,195, which includes, however, 68,701 men sent home as invalids, the majority of whom have recovered and resumed duty. The actual reduction of the military forces through the war is 25,962, which is made up as follows: Killed in action, 5445; died of wounds, 1903; died in captivity, 102; died of disease, 12,334; accidental deaths, 639; invalids sent home who have died, 479; invalids who have left the service unfit, 4988; missing and prisoners, 72. During last month the figures were: killed, 171; wounded, 463; missing, 18; died of disease, 525; accidental deaths, 41; invalidated home, 2367; total, 3585. The 528 deaths from disease compares with 536 in January, 351 in December, 236 in November, and 136 in October.

### Correspondence.

#### Philadelphia Municipal Hospital.

PHILADELPHIA, March 18, 1902.

*To the Editor:*—I was sorry to see in the issue of THE JOURNAL for March 15, under "Pennsylvania Notes," a manifestly untrue statement as to the action of the Philadelphia County Medical Society respecting the administration of the Municipal Hospital. This news item conveys an entirely wrong impression, as from my own knowledge, a vast majority of the members of the Society most cordially endorse and commend the splendid work accomplished in this Hospital, with its inadequate facilities. The facts are these: No business can be introduced at the scientific meetings of the Society, except by unanimous consent. As one member objected, I was obliged to rule against the admission of resolutions commendatory to the management of the hospital during the present epidemic of small-pox. Your correspondent must have taken his quoted sentence from the public prints, as no such language as that used by him appeared in the wording of the resolutions referred to.

Very truly yours, THOMAS H. FEXTON,  
President of the County Medical Society.

#### Displaced Heart.

BLOOMINGTON, ILL., Feb. 6, 1902.

*To the Editor:*—On November 27, 1901, G. W. H., late private in the Illinois Cavalry, came before the Board of U. S. Examining Surgeons at Bloomington, Ill., for examination for an increase of pension. He was born in Illinois, and has always lived in this state, except when he was in the Union Army from 1861 to 1864. He is 58 years old, weighs 150 pounds, and is 5 feet and 7¾ inches high; he has blue eyes, gray hair, light complexion, and is by occupation a carpenter. He complained of chronic rheumatism, disease of the digestive organs, abdominal hernia, injury to back, fracture of both bones of left leg, and debility from old age.

The apex impulse of the heart was evident on inspection and palpation in the fifth intercostal space one inch to the left of the right nipple line. The area of cardiac dulness was normal; the rhythm was regular; the action and sounds were normal, with no dilatation or hypertrophy. The only thing peculiar or unnatural was its anomalous position. This soldier was examined by the board about three years ago, at which time the malposition of the heart was first discovered.

In this case the apex of the heart is transposed to the right side and the base to the left side. The natural situation is simply reversed. The structure and function of the heart are normal. The arterial side is toward the left and the venous toward the right side.

In more than forty years as a student and practitioner of medicine I have never read or heard of a case similar to this. On account of its rarity I report it, thinking that it may be of interest to the profession.

JOHN LITTLE, M.D.,

Sec. Board of U. S. Examining Surgeons.

### Married.

SOLOMON S. LEE, M.D., to Miss Irene Childs, both of Calumet, Mich., March 11.

ROSCOE M. WOOD, M.D., Saline, Mich., to Miss Mattie Blaess of Lodi, Mich., March 12.

OSCAR M. GILBERT, M.D., to Miss Agnes Kirkbridge, both of Boulder, Colo., March 26.

E. ZEIGLER BOWER, M.D., to Miss Mary McMahon, both of North Scranton, Pa., March 14.

EDMUND F. BURTON, M.D., to Mrs. Alberta N. Hall, both of Oak Park, Ill., at Tucson, Ariz.

JESSE A. PRINGLE, M.D., Bagley, Iowa, to Miss Gertrude Swann of Lovilia, Iowa, March 19.

HUMBERT MEREDITH, M.D., Petroleum, Ky., to Miss Effie Wootten of Lafayette, Tenn., March 11.

JOHN J. REYCRAFT, M.D., Petoskey, Mich., to Miss Metta J. Cornell, of South Bend, Ind., March 19.

EDWARD GUION, M.D., Atlantic City, N. J., to Miss Sarah Edie Fleming of Yonkers, N. Y., March 18.

HENRY V. BERGHALL, M.D., Manistee, Mich., to Miss Margaret Evelyn Herron, at Elmwood Farm, Pumptown, near Metuchen, N. J., March 15.

### Deaths and Obituaries.

**Henry M. Skillman, M.D.** Transylvania University, Lexington, Ky., 1847, expired suddenly, from heart failure, while ministering to a patient at his office in Lexington, March 21, aged 78. He was one of the best-known and best-beloved physicians in Kentucky, and his loss comes as a personal one to a large number of the profession of Kentucky. He was born in Lexington, Sept. 4, 1824. He studied in the literary department of Transylvania University, from which he withdrew at the end of his junior year in order to prepare for the study of medicine. He spent a year in the drug store of his brother and then entered the medical department of Transylvania, from which he graduated in 1847. On graduating he was made demonstrator of anatomy, and later was called to the chair of physiology and pathological anatomy. He held this position until the buildings were burned during the Civil war. He was contract surgeon for the government for two years during the war. In 1869 Dr. Skillman was elected president of the Kentucky State Medical Society, and there have been very few meetings since then that he has missed. He was a member of the American Medical Association for about forty years, and was the first president of the Lexington and Fayette County Medical Society.

**George M. Warner, M.D.** Louisville (Ky.) Medical College, 1880, died suddenly at his residence in Louisville from angina pectoris, March 16, aged 44. He was born in Louisville, received his education in the public schools and graduated from the Male High School in the early 70's. For about two years after his graduation he was connected with the Louisville *Courier-Journal* as a reporter, but then entered on a course of study in the Louisville Medical College. For the five years after graduation he was lecturer on materia medica and therapeutics, and in 1885 was elected professor of these branches, which position he held up to the time of his death. He has been for ten years president of the Alumni Association of the Louisville Medical College, and since 1892 had been visiting physician to the Louisville City Hospital. From 1894 to 1899 he was editor of the Louisville *Medical Monthly*. He was a member of the American Medical Association. In 1886 Dr. Warner married Miss Hood, a daughter of the Confederate general, J. B. Hood; his widow and two children survive him.

**Russell B. Freeman, M.D.** College of Physicians and Surgeons, Baltimore, 1892, died at St. Anthony's Hospital in Denver, March 12, from appendicitis, after an illness of 10 days, aged 41. He was instructor in clinical medicine, Gross Medical College, and a member of the American Medical Association, Colorado State Medical Society, Denver and Arapahoe Medical Society, Rocky Mountain Inter-State Medical Society and Denver Clinical and Pathological Society. Resolutions on the death of Dr. Freeman have been sent to his family by the Denver and Arapahoe Medical Society, the staff of St. Anthony's, and of St. Joseph's hospitals.

**Dr. W. W. Johnston.**

William Waring Johnston was born in Washington, D. C., in 1843, and died suddenly, March 21, 1902, at Atlantic City, N. J., where he had gone for rest and recuperation after a slight illness. He studied medicine in the University of Pennsylvania, graduated in 1865, and served as interne in Bellevue Hospital for one year. Later, he studied at Edinburgh and Paris, and, on the death of his father, Dr. William Poynton Johnston, professor of obstetrics in the Columbian University, he became professor of the theory and practice of medicine in the same institution. He has been president of the old Clinical Pathological Society, Medical Society of the District of Columbia, Medical Association of the District of Columbia, and the Washington Obstetrical and Gynecological Society, likewise, member of the American Medical Association, the Association of American Physicians, American Climatological Society and the Anthropological Society. He was consulting or attending physician of the Children's, Garfield Memorial, University, Providence, the Asylum, United States and Emergency Hos-

WILLIAM WARING JOHNSTON.

pitals, Central Dispensary and Woman's Clinic. The faculty of the Medical Department of the Columbian University and the Medical Board of the University Hospital, at a special meeting, adopted and placed on record a suitable memorial. He was the attending physician to the late James G. Blaine, and was called in consultation in the case of President McKinley.

**John R. Timberlake, M.D.** Kentucky School of Medicine, Louisville, 1857, died of paralysis at his residence in Louisville, March 16. On March 6 Dr. Timberlake had a stroke of apoplexy which was followed by a second on the day of his death. He located in Pewee Valley, where he practiced for nearly thirty years. In 1888 he went to Louisville with the intention of retiring from active practice, but he did more work there than before. He was married in 1869 and five children survive him.

**Jonathan Woodward Goodell, M.D.** Berkshire Medical College, Pittsfield, Mass., 1856, one of the oldest practitioners of Lynn, Mass., died at his home in that place, March 12, from abscess of the liver, after an illness of four weeks, aged 71. At his funeral delegations were present from the Massachusetts

Medical Society, the Essex South Medical Association, and the Lynn Medical Fraternity.

**Albert R. Leeds, Ph.D.** College of New Jersey, 1878, professor of chemistry in Stevens' Institute, Jersey City, member of the State Board of Health and chairman of its council of analysts, an authority on food and water analysis and member of many scientific bodies, died from cancer of the stomach, March 13, at his home in Germantown, Pa., aged 58.

**John H. Christian, M.D.** Medical College of Virginia, Richmond, 1867, who served in the Civil war in Mosby's command, and at the close of the war studied medicine and settled for practice in Baltimore, died, March 13, from diabetes at the Virginia Hospital, Richmond, aged 55. He was a member of the American Medical Association.

**Charles G. Massie, M.D.** Medical College of Virginia, Richmond, 1860, an old and prominent physician of Goochland County, Va., and a veteran of the Civil war, throughout which he served on the Confederate side, died from paralysis at his home near Perkinsville, Va., March 12, after an illness of four days, aged 65.

**David F. Brown, M.D.** Washington University, St. Louis, 1873, a prominent physician of Dresden, Mo., one of the largest landowners in Pettis County, and a member of the board of managers of State Lunatic Asylum, No. 3, at Nevada, Mo., died at his home in Dresden, March 15, from pneumonia, aged 56.

**Lorenzo S. Keene, M.D.** New York University, 1846, formerly a practitioner and surgeon of the Lake Shore and Michigan Southern Railway at Laporte, Ind., but of late years retired from practice and residing in DeLand, Fla., died from pneumonia at his home in that place, March 18.

**Mare Livingston, M.D.** Cooper Medical College, San Francisco, 1875, a specialist on diseases of the throat and lungs, and in 1882 and 1883 coroner of San Francisco, died at his home in that city, March 14, after an illness of nearly five years, from paralysis, aged 44.

**George G. Williams, M.D.** Long Island College Hospital, Brooklyn, N. Y., 1876, one of the oldest practitioners in Hillsdale County, Mich., died at his home in Jonesville, March 16, from cancer of the stomach, after an illness of three months, aged 52.

**Benjamin F. Sutton, M.D.** University of Vermont, Burlington, 1860, a prominent physician and citizen of Addison County, Vt., died at his home in Middlebury, Vt., from pneumonia, March 11, after an illness of one week, aged 66.

**J. Baxter Upham, M.D.** Harvard Medical School, Boston, 1848, who served through the Civil war as a major-surgeon on General Burnside's staff, died from acute indigestion, at his home in New York City, March 17, aged 82.

**Mauricio W. Gillmer, M.D.** Jefferson Medical College, 1881, a native of Brazil, South America, where his father was American minister, died at his home in Philadelphia, March 17, aged 41. He had retired from practice in 1892.

**William Fontaine Lippitt, M.D.** Jefferson Medical College, Philadelphia, 1853, who had practiced in Charlestown, W. Va., for more than forty years, died at his home in that place after a prolonged illness, March 11, aged 70.

**Cornelius E. Satterfield, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1878, a physician of Omaha, Neb., died, March 11, from paralysis after a lingering illness, at Cook's Hospital, Fairmont, W. Va.

**Leroy Swank, M.D.** Rush Medical College, Chicago, 1885, a physician of Warren County, Ind., and secretary of the County Board of Health, died at his residence in Williamsport from pulmonary tuberculosis, March 17.

**Leonidas H. Eaton, M.D.** Rush Medical College, Chicago, 1874, died at his home in Oshkosh, Wis., March 16, from diabetes and heart disease, after an illness of four years, aged 52. He was city physician in 1882.

**John J. Clark, M.D.** University of California, San Francisco, 1869, a practitioner of San Francisco since 1877, at one time city physician, died at his home in San Francisco from paralysis, March 10, aged 58.

**Edward Newton Beale, M.D.** Berkshire Medical College, Pittsfield, Mass., 1864, for more than thirty years a physician of Rensselaer County, N. Y., died at his home in Schaghticoke, N. Y., March 16, aged 66.

**Joseph J. Fortier, M.D.** Ecole de Médecine et de Chirurgie, Montreal, Quebec, 1860, a physician of West Superior, Wis., died suddenly at his home in that place, March 17, from apoplexy, aged 62.

**John W. Hill, M.D.** University of Pennsylvania, Philadelphia, 1853, one of the oldest and most prominent physicians of Edgefield County, S. C., died suddenly at his home in Edgefield, March 13.

**James Murphy, M.D.** State University of Iowa, Iowa City, 1888, a young physician of Iowa City, died at his home in that city from typhoid fever, after a short illness, March 12, aged 37 years.

**Albert A. Becherer, M.D.** Marion-Sims Medical College, St. Louis, 1901, senior physician at the Female Hospital, St. Louis, died from septicemia at his rooms in that institution, March 8, aged 27.

**James R. Lyons, M.D.** Tulane University, New Orleans, La., 1882, a retired physician of Bagwell, Red River County, Texas, and a member of the twelfth legislature, died March 7.

**Alfred F. Fletcher, M.D.** Queen's Medical College, Melbourne, Australia, 1864, died at his home in Eau Claire, Wis., March 14, suddenly from heart disease, aged 57.

**George H. Lane, M.D.** Marion-Sims College of Medicine, St. Louis, 1895, died at his home in East St. Louis, Ill., March 18, from pneumonia, aged 28.

**Anson A. Gibbs, M.D.** University of Vermont, Burlington, a retired physician of Henlock, N. Y., died from paralysis at his home, March 16, aged 71.

**Allen T. Corliss, M.D.** Rush Medical College, 1894, a practitioner of Logansville, Wis., died at that place, March 19.

**E. L. Thorp, M.D.** Keokuk (Iowa) Medical College, 1877, died at his home in Shell Rock, Iowa, March 10.

## Book Notices.

**ODIOMYCOSIS (BLASTOMYCOSIS) OF THE SKIN AND ITS FUNGI.** By Howard T. Ricketts, Fellow in Cutaneous Pathology in Rush Medical College. Paper. Reprinted from *Journal of Medical Research*, Vol. VI, No. 3.

The conclusions of this monograph have been given already in *THE JOURNAL* of January 18, p. 204. In its reprinted form it makes a handsome volume of over 180 pages, elegantly illustrated. It is a noteworthy contribution to dermatologic literature.

**AN INTRODUCTION TO THE BACTERIOLOGICAL EXAMINATION OF WATER.** By W. H. Horrocks, M.B., B.Sc., Lond., Assistant Professor of Military Hygiene in the Army Medical School, Netley. Cloth. Pp. 300. Price, \$3.68 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This volume, which is intended to be a concise and readily understandable manual of methods of bacteriologic examination of water, divides water bacteria into three classes: Those which are found only in pure water, those which are common in sewage and hardly met with in pure water, those which are specially pathogenic to human beings. The preparation of water plates, collection of water for bacteriologic examination, the natural history of the organisms, the relation of quantitative analysis to the question of pollution, etc., are noticed and the different species described, especial attention being given to those of importance. The subject is a difficult one in some respects, the water bacteria being minute and often pleomorphic; yet, so far as we have observed, the author has handled his subject well.

**CLINIQUE DES MALADIES DU SYSTEME NERVEUX, HOSPICE DE LA SALPETRIERE (1897-1898, 1898-1899).** Cinquième and Quatrième Serie. Paper. Pp. 606 and 678, respectively. Price, 70 francs. Paris: Octave Doin. 1900 and 1901.

These two volumes are the latest of the series publishing Professor Raynaud's didactic lectures at the Salpêtrière. As in the earlier issues of this series they are not exactly parts of a systematic text-book on nervous disorders, but rather a succession of clinical lectures on various conditions published as they were delivered, but with numerous schematic and other illustrations. They do not form a treatise, but are instead a series of monographic studies of special subjects, and as such have a particular value.

Among the subjects included in the two volumes may be mentioned polio-encephalitis superior, various disorders attendant on or complicating tabes—such as ophthalmoplegia, muscular atrophy, etc.—affections of the conus terminalis, juvenile general paralysis, myxedema, partial epilepsy, cortical sensory centers, multiple sclerosis, etc. All of these are handled in a

masterly way and the volumes form a valuable contribution to neurologic literature. As usual with French writers the style is lucid and the illustrations are a valuable adjunct to the text. They can hardly be spared from the working library of the neurologic specialist.

## Association News.

### The Third Annual Conference of the Committee on National Legislation.

The Committee on National Legislation has sent to the delegates from the several State Medical Societies, the following call for the third annual conference to meet in Washington, D. C., April 10 and 11. Special attention is hereby called to the fact that this is the annual meeting and conference of the Committee on National Legislation, and must not be mistaken for a meeting of the Committee created by the new By-Laws of the Association, and known as the Committee on Medical Legislation, which is to meet with the Association at Saratoga in June next. Very truly yours, H. L. E. JOHNSON.

WASHINGTON, D. C., March 17, 1902.

*Dear Doctor:*—The Committee of the American Medical Association on National Legislation hereby requests you, as the delegate from your State Society, to meet this committee in annual conference at the Arlington Hotel, Washington, D. C., April 10-11, 1902, at 9 a. m. In the event of your inability to attend, please forward this notice promptly to your alternate. You should arrange early with Mr. Bennett, proprietor of the Arlington, for your accommodations. Street cars will take you direct from both depots to the hotel, obviating extortionate cab fare. Delegates are requested to present to the conference any matter, local or national, of interest to their State Society. The following will be submitted by this committee for your consideration, viz.:

Reports of Committees of the Second Annual Conference:

1. Committee on "Uniform legislation on basis of uniform medical education": Drs. Emil Amberg, Dudley S. Reynolds, John B. Roberts.
2. Committee on "State medical organization": Drs. C. R. Shinnault, W. P. Goff, L. B. Tuckerman, H. M. Bracken, Charles E. Quimby.
3. Committee on special Congressional Bills, last session: S. 4171, Quarantine Bill; H. R. 13423, Codification Postal Laws; Dr. L. B. Tuckerman.
4. Committee on Reorganization Bill: Dr. G. M. Sternberg.
5. National Committee ad interim. Annual report; Committee on National Legislation: Drs. H. L. E. Johnson, Wm. H. Welch, W. L. Rodman.

### NEW BUSINESS.

6. Official action of conference of State Health Officers at Washington, D. C., March 12-13, 1902, and their recommendations to Congress, and the third annual conference, in connection with pending National Health bills, viz.: Perkins Bill S. 2162, To increase the efficiency and change the name of the United States Marine Hospital; Hepburn Bill H. R. 7189, duplicate of Perkins Bill; Spooner Bill S. 2417, Relating to quarantine and public health; Ray Bill H. R. 10,595, To establish a board of public health and for other purposes.
7. Bills and Acts: Gallinger Bill, S. 189, For the further prevention of cruelty to animals in the District of Columbia; Nelson Bill, S. 569 (now an act of Senate with report 82), To establish the department of commerce and labor; Hay Bill H. R. 1952, To define the duties of the medical department of the Army of the U. S.; Kern Bill H. R. 7650, To re-establish the Army canteen; Proctor Bill S. 2172, To provide for the payment of medical expenses of sick officers and enlisted men of the Army while absent from duty with leave or furlough.
8. Communication from Dr. John J. Riley, U. S. Army, Manila, P. I., with proposed amendment to Sec. 18, of Act 4300, approved Feb. 2, 1901, bearing the endorsement of the Legislative Committee of the medical officers of the U. S. Army at Manila.
9. Reports of delegates (State Societies).
10. Miscellaneous.

Please acknowledge the receipt of this and notify me promptly whether you or your alternate will attend the conferences.

Very truly yours, H. L. E. JOHNSON, M.D.,  
Chairman Committee on National Legislation.

## Societies.

### COMING MEETINGS.

- American Association of Pathologists and Bacteriologists, Cleveland, O., March 28-29, 1902.
- Medical Association of the District of Columbia, Washington, April 1, 1902.
- Tri-State Medical Society of Iowa, Illinois and Missouri, Chicago, April 3-4, 1902.
- Tennessee State Medical Society, Memphis, April 8, 1902.
- Florida Medical Association, Tampa, April 9, 1902.
- Western Ophthalmological and Oto-Laryngological Association, Chicago, April 10-12, 1902.
- Medical Association of the State of Alabama, Birmingham, April 15, 1902.
- Medical Society of the State of California, San Francisco, April 15-17, 1902.
- Medical Association of Georgia, Savannah, April 16, 1902.

Mississippi State Medical Association, Jackson, April 16, 1902.  
South Carolina Medical Association, Spartanburg, April 16-17, 1902.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.

Association of American Physicians, Washington, D. C., April 29-30, 1902.

American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.

International Association of Railway Surgeons, St. Louis, Mo., April 30 and May 1 and 2, 1902.

American Gastro-Enterological Association, Washington, D. C., May 2, 1902.

Nebraska State Medical Society, Omaha, May 6-8, 1902.

Texas State Medical Association, Dallas, May 6-9, 1902.

Kansas Medical Society, Lawrence, May 7-9, 1902.

American Therapeutic Society, New York City, May 13, 1902.

Utah State Medical Society, Salt Lake City, May 13-14, 1902.

New Mexico Medical Society, Albuquerque, May 14, 1902.

Oklahoma Territory Medical Association, Oklahoma City, May 14, 1902.

Arkansas Medical Society, Little Rock, May 14-16, 1902.

New Hampshire Medical Society, Concord, May 15-16, 1902.

**Panhandle (Texas) Medical Association.**—This Association met at Quanah, March 12, and re-elected Dr. David R. Fly, Amarillo, president, and Dr. T. H. Carroll, Clarendon, secretary.

**Louisville (Ky.) Clinical Society.**—The regular meeting of the Louisville Clinical Society was held, March 11. Dr. M. K. Allen, health officer, read a paper on "Diphtheria," in which he gave the statistics of a severe epidemic in Louisville last year.

**Chattanooga (Tenn.) Medical Society.**—At the annual meeting of this Society, March 7, Dr. Benjamin F. Travis was elected president; Dr. Charles S. Durand, vice-president, and Dr. Joseph W. Johnson, secretary, and Dr. Samuel T. Rucker, treasurer.

**West Chicago Medical Society.**—This Society gave its first annual banquet, March 6. Dr. Emil D. St. Cyr acted as toastmaster, and those who responded were Drs. David Birkhoff, O. Martin Steffensen, Edward H. Lee, Benjamin H. Breakstone and Gustavus M. Blech.

**Page County (Iowa) Medical Society.**—Physicians of Page County met at Shenandoah, February 25, and organized a county medical society, electing Dr. Tilford L. Putnam, Shenandoah, president; Dr. Sellard, Clarinda, secretary, and Dr. Clark, Shambaugh, treasurer.

**Practitioners' Club (Louisville, Ky.).**—The annual meeting of this Society was held, March 11, the election of officers resulting as follows: President, Dr. James E. Guest; vice-president, Dr. Frank T. Fort; secretary and treasurer, Dr. Hugh R. Manning; historian, Dr. John J. Moren. A banquet was served at the conclusion of the business session.

**New Medical Society at Columbus.**—A meeting of Columbus physicians took place, March 18, under the chairmanship of Dr. Christopher P. Linhart. The following officers were elected: Dr. David N. Kinsman, president; Drs. John C. Bishop and Frank S. Rarey, vice-presidents; Dr. Charles S. Means, secretary, and Dr. Sherman Leach, treasurer.

**St. Clair County (Ill.) Medical Society.**—The following officers were elected at the annual meeting of this Society, held at East St. Louis, March 6: Dr. Henry C. Fairbrother, East St. Louis, president; Dr. Charles W. Lillie, East St. Louis, recording secretary; Dr. Adolph E. Hansing, East St. Louis, treasurer, and Dr. Buenavandura H. Portuondo, Belleville, corresponding secretary.

**San Joaquin Valley (Cal.) Medical Society.**—This Society held its thirteenth semi-annual session at Fresno, March 11, electing officers for the next term as follows: First vice-president, Dr. John B. Rosson, Tulare; second vice-president, Dr. Claiborne W. Evans, Modesto; third vice-president, Dr. A. B. Cowan, Fresno; secretary, Dr. W. S. Fowler, Bakersfield; assistant secretary, Dr. Dwight H. Trowbridge, Fresno, and treasurer, Dr. Thomas M. Hayden, Fresno. A committee was appointed to confer with the other local societies and with the committee of the state society on reorganization to better affiliate with the American Medical Association.

**Saratoga County (N. Y.) Medical Association.**—The semi-annual meeting of this Association was held at Ballston Spa, March 11. Eleven new members were elected. The topic selected for discussion was "Puerperal Sepsis," Dr. Dudley R. Kathan, Corinth, taking up the etiology and prophylaxis; Dr. Walter C. Crombie, Mechanicsville, the symptoms and diagnosis, and Dr. George Hudson, Stillwater, complications, their diagnosis and treatment. Dr. Frank A. Palmer, Mechanicsville, was elected president; Dr. Henry J. Allen, Corinth, vice president; Dr. James F. Sweetman, Jr., Ballston Spa, secretary, and Dr. William E. Swan, Saratoga Springs, treasurer.

## NEW YORK ACADEMY OF MEDICINE—SECTION ON PEDIATRICS.

*Stated Meeting, held Feb. 13, 1902.*

Dr. Rowland G. Freeman, in the Chair.

### Acquired Syphilis in a Girl of Eight Years.

DR. SARA WELTKAKELS presented a girl aged 8, with a macular syphilid on the body, and a general and marked adenopathy. The initial lesion was upon the clitoris.

### Stomatitis Due to Vincent's Bacillus.

DR. HENRY HEIMAN exhibited two children having an ulceromembranous stomatitis characterized by the presence of Vincent's bacillus and the spirillum of Miller. He said that the bacillus could be readily demonstrated by a smear stained with carbol-fuchsin.

DR. E. LIBMAN contended that it had not yet been proved that these bacilli were characteristic of any particular disease, and that these organisms seemed to be associated with destruction of tissue. Their presence would not necessarily exclude syphilis, though it might rule out diphtheria.

### Pathology of Adenoids and Tonsils.

DR. A. J. LARTIGAU took up in this paper some of the more important practical points in connection with the pathology, dwelling more particularly on tubercular infection of the tonsil. It was, he said, a very common secondary lesion in connection with pulmonary tuberculosis with cavity formation. Primary tuberculous of the tonsil was rare.

### Operative Treatment of Adenoids and Enlarged Tonsils.

DR. W. K. SIMPSON advocated the surgical removal of all adenoids and enlarged tonsils when of sufficient size to give rise to symptoms. The presence of adenoids was often the cause of repeated attacks of coryza, spasmodic croup and bronchitis, and was almost the sole cause of middle ear deafness in suppurative otitis media. The vault of the pharynx should always be explored with the finger before operating. Whether to use the curette or the forceps was a matter of individual opinion. Personally, he was in favor of the forceps because they bring away a larger piece and enable the operator to see how much has been removed, but for small children the curette was probably the safer instrument. The forceps should be strong and rather large, with a sufficiently extensive cutting surface and a shield to protect the uvula and posterior border of the soft palate from injury. The Gradle forceps, as modified by Concannon, could be confidently recommended. The child should be held upright with a mouth-gag to keep the mouth open. The forceps are introduced closed; then opened widely and pressed well upward and behind, and the mass seized and the forceps withdrawn. The operator should not neglect to again introduce the finger in order to ascertain if any has been left behind. Of the various curettes, some modification of the Gottstein was usually employed. Recurrences of adenoids occurred in only a small proportion of cases. For the performance of tonsillotomy, Dr. Simpson favored the use either of Ermed's simplification of the Mathien tonsillotome or of the very simple, strong and efficient tonsillotome of Mackenzie. On introducing the instrument, pressure should be constantly made with the finger outward upon the shaft, while at the same time the assistant by external pressure pushes the tonsil into the ring of the instrument. Hemorrhage need give no cause for anxiety, for it is a very rare complication of tonsillotomy in children, and could usually be controlled by the application of peroxid of hydrogen or of a solution of suprarenal extract. Adrenalin rendered particularly valuable service in the removal of tonsils from older children and adults, but it should be remembered that there was some tendency to secondary hemorrhage after its use. Irrigation, spraying and the insufflation of powders were usually to be avoided after these operations, if only because they caused undue motion of the throat. Cracked ice may be swallowed at short intervals, or ice may be applied to the throat externally. The patient should remain in the house and keep quiet for several days, and during this time the diet should be light, and care should be taken not to eat bread-crusts, dry crackers or pieces of meat. The speaker said that while an anesthetic seemed essential to a

careful and thorough removal of adenoids, he was not in favor of employing anesthesia for a tonsillotomy, principally because the gagging of the patient materially assisted the operator in bringing the tonsil into view.

#### Recent Contributions on the Constitutio Lymphatica.

DR. JAMES EWING said that, clinically, children of this type often died very suddenly and unexpectedly, and during life they presented certain important signs, viz., 1, general lymphatic hyperplasia; 2, persistence of the thymus; 3, hyperplasia of the aorta and sometimes of the heart; 4, evidences of rachitis; 5, evidences of retarded development of various organs; 6, enlargement of the thyroid, and 7, general neurotic tendencies. Recent observations had called attention to the presence of an atrophic stage of the lymphatic diathesis, and the relation of the latter to the various types of lymphatic tuberculosis certainly demanded more careful study. In cases of constitutio lymphatica, nervous symptoms were present throughout the course of the disease, and laryngismus stridulus occurred almost exclusively among these subjects. Dr. Ewing laid special stress upon the great danger of giving chloroform to children afflicted with constitutio lymphatica, and asserted that there was reason for believing that chloroform was rarely, if ever, fatal except in this class of persons.

#### Surgical Treatment of Enlarged Lymph Nodes.

DR. CHARLES N. DOWD presented a paper on this subject. He favored the surgical removal of tubercular lymph nodes as soon as the diagnosis was made. The incisions could be so arranged that the operation scars would be less disfiguring than those left after abscess formation. Of his own operative cases, 23 had been apparently cured and 47 improved.

DR. A. JACOBI said that while of course all agreed as to the propriety of removing adenoids when large, there was room for an honest difference of opinion in cases in which the adenoids were so small as not to cause snoring. He personally did not believe in operating in the latter class, for, a large experience had taught him that by simply irrigating the parts twice daily with saline solution or with a solution of boric acid, all need for an operation would disappear. He had discovered that it was the habit of nasal specialists to neglect all after-treatment after removal of adenoids, and to this would he ascribe the occurrence of relapses. In operating upon adenoids he did not use an anesthetic, because in order to control the masseter muscles the anesthesia must be pushed to a dangerous degree. The mother or assistant should hold the child, and the head of the little patient should be buried between the thighs of the operator. With a curette the operation could be completed in a minute, and anesthesia was unnecessary and inadvisable.

DR. FRANCIS J. QUINLAN took issue with Dr. Jacobi regarding the treatment of the milder cases of adenoids. The nasal irrigations recommended by Dr. Jacobi were dangerous because of the liability of forcing secretions into the middle ear; moreover, it seemed to him that these irrigations were absolutely useless, for they only served to force the secretions back to whence they came, i. e., the rhinopharynx. The occurrence was no indication of nasal obstruction, as it might be due to the dropping back of the tongue or to vibration of the soft palate.

DR. HENRY D. CHAPIN narrated a case in confirmation of the position taken by Dr. Jacobi that the mild cases of adenoids would recover without operation under simple irrigations.

DR. W. K. SIMPSON objected to such treatment on the ground that many cases, seemingly mild at first, became formidable later by the development of an otitis media.

#### DENVER AND ARAPAHOE MEDICAL SOCIETY.

*Regular Meeting, Held Feb. 11, 1902.*

Dr. Edward Jackson, in the Chair.

#### Bronchial Obstruction in Phthisis.

DR. J. N. HALL said that bronchial obstruction by enlarged bronchial glands must be much more frequent clinically than it is assumed to be.

CASE 1.—Male, 34 years, had left pulmonary tuberculosis for six years, suffered for last three months from dyspnea and

cyanosis on slight exertion. Chest retracted on inspiration. Over the left lung diminished respiratory murmur and vocal fremitus, marked inspiratory creoning. These signs persisted for about three weeks and gradually disappeared without notable increase in expectoration. There were no signs of aneurysm nor of intrathoracic tumor.

CASE 2.—Male, aged 20, had old ankylosis of right hip. Cough since 11 years of age, when he had an attack of pneumonia. Dulness was over right apex. Respiratory murmur and vocal fremitus decreased, marked inspiratory dyspnea, harsh inspiration; left pupil slightly larger than right. Patient was treated like one with acutely enlarged scrofulous glands in the neck with large doses of iodid of iron. In a few days the cyanosis and dyspnea had disappeared.

The subsidence of all symptoms of dyspnea and cyanosis in the above two cases is explained by the removal of pressure from the enlarged glands upon the bronchi, in the first case by suppurative process and in the second by absorption.

#### Rheumatic Creaking in Shoulder Joint in Phthisis.

DR. J. N. HALL reported two cases in one of which a superficial examination may have led to an erroneous diagnosis of pulmonary tuberculosis, while in the other the creaking was associated with this disease.

#### Iliac Vein Thrombosis After Typhoid.

DR. J. N. HALL reported the above condition in a man of 37 years, who fifteen years ago had typhoid fever. His left leg remained slightly enlarged. From the left groin two veins each as large as a lead pencil ran transversely to the right side. The great size of the collateral vessels leads him to think that the venous path to the vena cava inferior was antrally cut off by upward extension of crural thrombosis. In another case a similar condition exists in the right leg.

#### Embolism of the Bifurcation of the Aorta.

DRS. W. E. SHOTWELL and J. N. HALL reported the following case: Male, 30 years of age. Valvular heart disease for years. Was suddenly awakened with terrible pain in the legs, which became blue and cold, no pulsation in femoral arteries. Heart enlarged, loud apex systolic murmur. Dyspnea, pulse 120. It is obvious that an instantaneous obstruction of the crural circulation had occurred at the time of his sudden pain. Patient died about thirty-six hours after the attack. Both legs were black, almost gangrenous, for some hours before the fatal result.

#### A New Canula for Paracentesis.

DR. JOHN S. MILLER, in presenting to the Society his ingenious invention, said:

The frequent occlusion of the canula by intestine or omentum in the operation of tapping in ascites has suggested this device. Various maneuvers are resorted to, such as changing the patient's position, or the dangerous one of introducing a probe through the canula, generally without success.

This device is simply an addition to the ordinary trocar and canula. The instrument is a smaller but longer canula introduced into that already in position in case there is a cessation of flow. It is blunt and provided with two fenestra. In the latter are two springs which expand and push or hold aside the obstruction on emerging from the original canula, and which are so firmly soldered as to afford no danger of breaking off in the abdominal cavity. Dr. Miller filled the abdominal cavity of a cadaver very tensely with water and had the intestines moderately inflated, thus imitating as nearly as possible the conditions in life. The cadaver was also placed in the position ordinarily used in tapping the abdomen. All efforts by various manipulations failed to catch the bowel or omentum. As a further and practical verification of the absolute safety of this instrument, he has used it over one hundred times, and in all this experience has never encountered any untoward features. With this instrument it is possible to withdraw at least 30 per cent. more fluid than with the ordinary trocar. The fluid runs off very slowly as compared with the flow of the larger trocar, owing to its smaller caliber. The inside canula is not introduced until the flow ceases from the obstruction floating against the mouth of the primary canula. This instrument can be made to fit any canula above caliber 16 French.

## Therapeutics.

### Gastric Ulcer.

Professor Robin of Paris, as noted in *Ther. Gazette*, gives the following in the treatment of gastric ulcer: For the relief from the pain which usually comes on after the ingestion of food or due to the excessive secretion of hydrochloric acid, the following is recommended:

|                                |         |       |
|--------------------------------|---------|-------|
| R. Pierotoxin                  |         |       |
| Morphinae hydrochlor., āā..... | gr. i   | 06    |
| Atropinae sulph. ....          | gr. 1/5 | 012   |
| Ergotin .....                  | m. xx   | 1 30  |
| Aq. laurocerasi .....          | 3iii    | 11 25 |

M. Sig.: Four or five drops before each meal in water.

The foregoing mixture dulls the sensitiveness of the stomach toward the irritating contact of the milk or solid food. According to the author the pain is not always relieved by such prophylactic treatment; in such cases a powder should be prescribed which will neutralize the excess of acid which may cause the pain. For this purpose he recommends the following:

|                           |          |      |
|---------------------------|----------|------|
| R. Lactose .....          | gr. xx   | 1 30 |
| Magnesia (calcined) ..... | gr. xxx  | 2 00 |
| Bismuthi subnit.          |          |      |
| Creta preparata, āā.....  | gr. x    | 66   |
| Codeinae .....            | gr. 1 10 | 006  |
| Sodii bicarb. ....        | gr. xx   | 1 30 |

M. Ft. Chart. No. i. Sig.: One such to be taken in a little water to relieve the pain.

In case the above does not relieve the pain, the following preparation containing cocaine may be prescribed:

|                         |       |      |
|-------------------------|-------|------|
| R. Cocaina hydrochlor.  |       |      |
| Codeinae, āā.....       | gr. i | 06   |
| Spts. chloroformi ..... | 5ii   | 7 50 |
| Aque calcais.....       | 3viii | 240  |

M. Sig.: One tablespoonful to be taken occasionally for the relief of pain.

He regards external applications of service in relieving pain and recommends the following liniment for local application:

|                                |      |      |
|--------------------------------|------|------|
| R. Linimenti belladonnae ..... | 3iss | 45   |
| Ext. opii                      |      |      |
| Ext. belladonnae               |      |      |
| Ext. hyoseyami, āā.....        | 3ss  | 1 90 |
| Spts. chloroformi .....        | 5ii  | 7 50 |

M. Ft. linimentum. Sig.: To be applied to the epigastric region.

He states that the application of a liniment in this form often proves effective in relieving the distress of the patient when internal treatment has proved ineffective.

For the vomiting, he recommends the above prescription containing pierotoxin and the application of a small blister to the epigastrium. If these fail a powder containing two grains of pulverized opium may be given or an inhalation of oxygen gas. In some cases the only means by which vomiting can be checked is to return to the rest cure. In the treatment of constipation, which is a very frequent complication, laxatives and enemata of warm water should be given. He advises the administration of oleum ricini, or the following:

|                                  |        |      |
|----------------------------------|--------|------|
| R. Hydrarg. chloridi mitis ..... | gr. vi | 39   |
| Pulv. jalapae .....              | gr. vi | 39   |
| Magnesia (calcined) .....        | gr. xv | 1 00 |

M. Ft. cachet No. i. Sig.: At one dose.

Or the following may be given:

|                           |         |      |
|---------------------------|---------|------|
| R. Pulv. aloes .....      | 3ss     | 1 90 |
| Resinae scammonii         |         |      |
| Pulv. jalapae, āā.....    | gr. xv  | 1    |
| Ext. hyoseyami            |         |      |
| Ext. belladonnae, āā..... | gr. iii | 20   |
| Saponis, q. s.            |         |      |

M. Ft. pilulae No. L. Sig.: One or two to be taken at bedtime.

For the diarrhea which infrequently accompanies ulcer of the stomach, Dr. Robin recommends pulverized eunonymi radix in doses of thirty grains, infused in a little water and taken

after meals. This may be repeated several times in the twenty-four hours if necessary, as it is non-toxic.

When hemorrhages occur, which naturally accompany gastric ulcer, the patient must be placed on his back, instructed to remain absolutely quiet and apply ice to the epigastric region. Subcutaneously, a solution of ergotin may be injected hypodermically, and gelatin may be administered in the same fashion in the following form:

|                      |        |      |
|----------------------|--------|------|
| R. Gelatin .....     | 5i     | 3 75 |
| Sodii chloridi ..... | gr. xx | 1 30 |
| Aq. destil. ....     | 3vi    | 180  |

M. Sig.: Inject six drams subcutaneously.

Internally the following should be prescribed:

|                                |       |      |
|--------------------------------|-------|------|
| R. Ergotin .....               | 5i    | 3 75 |
| Acidi gallici .....            | gr. x | 66   |
| Syrupi terebinthinae .....     | 3i    | 30   |
| Aque onethi (dill-water) ..... | 3iv   | 120  |

M. Sig.: One teaspoonful every hour.

Alternating with the foregoing the following may be given:

|                          |       |      |
|--------------------------|-------|------|
| R. Calcii chloridi ..... | 5i    | 3 75 |
| Ext. opii .....          | gr. i | 06   |
| Syrupi simplicis .....   | 3i    | 30   |
| Aque .....               | 3iv   | 120  |

M. Sig.: One tablespoonful every hour.

The chlorid of calcium is said to have the property of increasing the coagulability of the blood. In case the hemorrhage should recur the patient must be placed upon the absolute rest cure for a period of nine days at least. In case of syncope following hemorrhage he recommends injections of ether or the normal saline solution. He states that the mortality when treated medicinally is about 9 per cent., while it is 20 per cent. in cases operated on. However, certain complications as perforation, etc., require surgery.

### Gonorrheal Vaginitis.

*Mercr's Archives* recommends the following in the treatment of gonorrheal vaginitis:

|                                   |        |       |
|-----------------------------------|--------|-------|
| R. Hydrastin hydrochloratis ..... | gr. xv | 1     |
| Aque q. s. ad. to dissolve.       |        |       |
| Adipis lanae hydrosi .....        | 3iv    | 15 00 |
| Copaiba .....                     | 3i     | 3 75  |
| Petrolati .....                   | 3iv    | 15 00 |

M. Sig.: Saturate absorbent cotton and pack the vagina night and morning after irrigating.

The following may be employed for irrigation:

|                                 |     |    |
|---------------------------------|-----|----|
| R. Potassii permanganatis ..... | 3ii | 60 |
|---------------------------------|-----|----|

Sig.: One-half teaspoonful in two quarts of warm water as a vaginal douche morning and night.

Or the following may be substituted as a douche:

|                             |     |     |
|-----------------------------|-----|-----|
| R. Pulv. aluminis           |     |     |
| Pulv. acidi borici, āā..... | 3iv | 120 |

M. Sig.: Two teaspoonfuls to the quart of water as a douche for children; four teaspoonfuls to the quart for adults. Use as a douche night and morning.

Where a more astringent wash is desired the following will be of service:

|                       |     |     |
|-----------------------|-----|-----|
| R. Acidi borici ..... | 3iv | 120 |
| Acidi tannici .....   | 3ii | 60  |

M. Sig.: Three teaspoonfuls to the quart of water as a douche twice a day.

As a vaginal antiseptic in the form of suppositories the following is recommended:

|                            |     |      |
|----------------------------|-----|------|
| R. Ichthyol .....          | 5i  | 3 75 |
| Iodoformi .....            | 5i  | 3 75 |
| Acidi tannici .....        | 3ss | 1 90 |
| Adipis lanae hydrosi ..... | 5i  | 3 75 |
| Olei theobromae q. s. ad.  |     |      |

M. Fiant suppos. No. vi. Incorporate the ichthyol in the wool fat and mix with cocoa butter and iodoform, then add the tannic acid. Sig.: Insert one suppository twice daily after a warm antiseptic boric acid solution.

### Intestinal Toxemia.

The *Indian Med. Rec.*, in an article on intestinal toxemia, regards it as a primary source of much disease, due to the absorption of gases and fluids from the intestinal canal, causing the destruction of the red corpuscles, and irritation of the

nervous system. The symptoms are headache, cardiac irregularities, insomnia, etc. The indications are to remove the poisonous material by frequent colonic flushings. For this purpose large enemas of normal saline solution may be employed.

Supplementing this treatment medicines acting on the liver and small intestine should be given in order to produce a sufficient flow of bile. The diet must be carefully guarded. Fresh fruit juices, nourishing broths, rice and cereals thoroughly cooked, baked apples and bananas, broiled beef pulp and asparagus seem to agree in the majority of cases.

## Medicolegal.

**Waiver of Privilege When Several Physicians Are Employed.**—Section 836 of the New York Code of Civil Procedure, in effect, provides that the information acquired by a physician while attending a patient may be disclosed only when the provisions of Section 834 on the subject "are expressly waived upon the trial \* \* \* by the patient." The United States Circuit Court of Appeals, Second Circuit, holds, with regard to this, in *Metropolitan Street Railway Company vs. Jacobi*, that it is not at liberty to depart from the construction placed upon the statute by the state court of last resort. Hence, it holds that the testimony of a physician who had been employed professionally by the latter-named party was properly excluded, when it was sought to elicit from him information received by him while attending such party in a professional capacity, the waiver claimed consisting in the fact that the party had called upon the trial as witnesses in his behalf three physicians who had attended him professionally, and who had given testimony in respect to the nature and extent of the injuries which were the subject of the action. But it says that if their testimony, or the testimony of any of them, had been in respect to information obtained at the same consultation or occasion at which the first-mentioned physician was present, the party would have waived the privilege to insist that such physician should remain silent, according to the construction given to the code provisions by the highest court of the state.

**Burden of Proof in Malpractice Case.**—The Supreme Court of Georgia holds, in *Georgia Northern Railway Company vs. Ingram*, that in an action for damages alleged to have been caused by the malpractice of a surgeon, the burden is on the party suing to show a want of due care, skill, or diligence, and also that the injury resulted from the want of such care, skill or diligence. Indeed, it says that, so far as it is informed, the authorities are uniform to this effect. Nor does it consider that the rule as to the burden of proof was changed by the fact that the surgeon who was alleged in this case to have been neglectful and unskilful in his treatment of the party who brought the action (*Ingram*) was not himself sued, but the action was brought against the railway company, under the allegation of the party that the company had contracted with him and other employes that, for 50 cents per month, it would furnish a skilled surgeon to attend him in case of sickness or accident. The testimony of this party and his witnesses was that the surgeon appointed by the company was called on Saturday and dressed his wound, saying there was no danger of losing the leg. He did not return until Tuesday or Wednesday. After that he sent his brother to dress the wound. This brother washed the wound in water so hot as to give the patient great pain, and then bound it so tightly with bandages as to cause excessive pain and suffering. The patient suffered greatly for two days, when the surgeon returned, and upon examining the wound, said it was in bad condition. On Saturday he amputated the limb, saying that his brother had bound it up too tight, though this last was denied by the surgeon. Under these circumstances, the court holds that the party failed to carry the burden of proof imposed upon him by the rule stated, and that the evidence did not authorize a verdict in his favor. Even if it be considered that it was negligence on the part of the surgeon to send his brother to dress the wound, who used

on it very hot water, and bandaged it so tightly as to cause the patient great pain, as testified, the court says that the evidence utterly failed to show that the necessity for the amputation was caused thereby. Nothing was shown in the evidence as to who the surgeon's brother was, whether he was a physician, or whether he had any skill or experience in dressing wounds. True, the petition alleged that this brother was merely a young medical student; but the company's answer denied this, and the evidence failed to show it. So far as could be told from the brief of evidence, he might have been an expert surgeon. But however this might be, the court does not think the party sustained the burden of proof upon him by showing a want of due care, skill, or diligence, and also that from such want of care, skill, or diligence resulted the necessity for the amputation of his leg; in consequence of which it reverses a judgment rendered in his favor.

**Expert Testimony—Want of License—Malpractice Damages.**—The Supreme Court of New Hampshire holds, in the malpractice case of *Challis vs. Lake*, that, to discredit the testimony of the party sued, who claimed and testified that he had had much experience in the practice of medicine, and was an ordinarily skilful physician, it was within the legitimate range of cross-examination, at least, to prove by his admission on the witness stand that he did not have a license, obtained after an examination as to his medical knowledge, to practice medicine when he had charge of the case in question, as required by law. That fact, if unexplained, would afford ground for the argument that his testimony as to his qualifications was entitled to little weight. The evident purpose of the statute was to prevent incompetent persons from practicing medicine and imposing upon the credulity of their unsuspecting patients. The expert testimony of a physician who has not complied with the statute and obtained a license might not be entitled to as much weight as it would otherwise receive, and the degree of credibility attached to it by the jury would often depend very much upon the reason he might assign for his noncompliance with the statute. If he honestly believed that for some reason he was exempted from a compliance with the statutory provisions, the fact that he did not have a license might have little weight upon the question of the soundness of his expert testimony. But the admissibility of the evidence on cross-examination, in disparagement of his credibility as a witness, could not be doubted. The question of the validity of the statute was immaterial. Whether it was void or not, it was competent for the jury to consider the unexplained omission of the witness to obtain a license, upon the question of the reliability of his testimony. Such a reason for his omission as that he was unable to pass the required examination, or that he failed on some ground to satisfy the regent and the board of examiners that he was entitled to a license or registration as a physician, if true or if believed by the jury, would have the same logical and legal effect in disparagement of his direct testimony, whether the statute were constitutional or not. That two nurses were not allowed to testify how the treatment of the party sued in cases of the kind in question differed from that of other physicians, the court holds, was not error. While they had nursed in cases where he had charge and in cases where other physicians attended, it says that the proposed testimony may have been excluded on the ground of remoteness, there being nothing in the case indicating that such was not the fact. Whether it might not have been properly excluded on other grounds, it says that it was unnecessary to decide. Loss or injury directly and naturally resulting from the fault or negligence of the party sued in his treatment of the case, the court holds, was the legitimate measure of the damages recoverable. His liability was not confined merely to damages for injuries which an ordinary man might have expected would follow from the negligence proved, but included damages for such injuries as were the direct and natural result thereof, as disclosed by the evidence. As the jury was instructed, this would include payment for all loss of time and for suffering that was caused by the fault of the party sued, but not for the loss of time and the suffering which were the result of the patient's confinement, it being a confinement case.

3. **Uric Acid.**—The origin of uric acid and its action in the system are noticed by Tyson, who finds that it is one of the end-products of animal metabolism just as much as urea, but not an intermediate product as was at one time supposed. It is remotely derived from the food ingested. This also is analogous to urea. He goes over the pathologic significance of uric acid and finds that its defective elimination in gout is probably due to some functional or organic defect of the kidneys, that its harmfulness is limited to the formation of concretions, and ascribes to the alloxuric bases the harmful phenomena of the so-called uric acid lesions. The so-called uric acid lesion exists in the excess of the sum of uric acid and the alloxuric bases and this is due to perversion of nuclein metabolism, which may be brought about by excessive or deficient oxygenation, the former producing both uric acid and alloxuric bases, and the latter an excess of alloxuric bases only. A large number of ills that are charged to uric acid are not thus caused, in the author's opinion. The so-called uric acid diathesis is probably hereditary, but is aggravated and produced

by over-eating and especially by the use of alcohol. As regards treatment, abundance of alkaline or plain water between meals, the exclusion of proteid foods, to an extent sufficient to eliminate uric acid from the urine, accompanied by a liberal amount of outdoor exercise, is still the treatment of the uric-acid diathesis. In conclusion, he quotes Croftan's outline of the treatment, as published in THE JOURNAL A. M. A. in 1899.

5. **Trifacial Neuralgia.**—Barber reports a case of pure tic douloureux relieved by 1/10 mg. dose of aconitin given every four hours until the patient had taken ten granules, followed by iron and simple tonic. The conclusions he deduces are: "1. That aconitin does really seem to be a specific; and 2, that its action must be maintained by a restorative."

7. **Specific Medication.**—Smith argues for the use of specific medication, quoting the use of creosotal in pneumonia, which he considers one of the greatest life-saving discoveries of the century just ended. He also mentions the use of carbolic acid for la grippe and claims that its comparative innocuousness in some conditions has been shown by observations of his own some years ago. Other remedies are also mentioned.

12. **Alcohol as a Therapeutic Agent.**—Hewes, in a carefully written paper, maintains that alcohol is a narcotic or anesthetic and that its action on the nerve cells is directly poisonous. He finds that as a stimulant it is insufficient and in continued doses is not a tonic to nerves or muscles. As a narcotic it has a certain value, but whether it is a useful narcotic and, if useful, in what cases, must be determined by therapeutic experience. It is to this special influence of alcohol, he holds, that the majority of medicinal effects, variously interpreted as stimulative or tonic, are due, always excepting the momentary irritant action. As a stomachic he finds it of little value. It may stimulate the appetite by its pleasant taste and slight irritant action. As a food in health it can play no part. In pathologic conditions the matter may be different and there may be cases where no other food can be taken. In fever, oxidation is more active and this may account for the commonly reported observation that patients with fever can take more alcohol than people in health. This, however, is only a question of an immunity to the poison, not the loss of the poisonous action of the drug. His study of the pharmacology and experimental work upon alcohol proves to him that it is never a heart stimulant or dynamogenic for nerve and muscle, but always a depressant when used continuously. He would not say that it has no value as a therapeutic agent in medicine or that its medicinal use is irrational, but he thinks that careful observation has led to a gradual restriction of its use so that the quantity given per capita is less than one-half that employed twenty years ago and that it will be still further reduced.

13. Shattuck affirms that in his experience alcohol is of value in disease; that many people can take it in large doses without the ill effects noticed from it in health and that its use as a medicine in acute diseases involves very little risk of establishing a vicious habit. He says there is not sufficient proof of the uselessness of alcohol to warrant us in running contrary to the mass of evidence on which belief in its value rests.

14. Whittier follows the same line of thought as Shattuck.

15. Cutler holds that alcohol is no protective against infection, no antipyretic, no stomachic, and no analeptic and its action as a food is embarrassed by its poisonous quality. That it can favor the immunization process is denied. His article takes the extreme anti-alcohol view as regards its value as a food or a medicine.

16. **Hydrotherapy.**—Putnam and Fitz report the results of experiments to determine the physiologic effects of different kinds of baths. They describe their methods, including the use of a hot cabinet and a circular rain douche. The effect of the hot bath is a marked diminution in the blood pressure, sometimes amounting to as much as 20 mm. of mercury. The normal pressure is almost immediately regained on leaving the hot bath, owing to the reverse process of peripheral constriction

due to the chill of rapid evaporation of water from the surface of the body. The pulse rate is markedly changed. We must recognize that the baths exert a strong influence on the control of the heart's rapidity and force and of the vasomotor changes of the vessels. Further experiments will be required, however, to clear up all the physiologic effects of the various modifications of the bath, especially as regards temperature and blood pressure. The clinical conditions which were tested were neurasthenia, tabes and other spinal diseases, paralysis agitans and neuritis. In neurasthenics he thinks this form of treatment is usually of distinct service. The method has been the employment of one or another form of so-called tonic baths, varied to suit the individual case. The mental effects, he thinks, have had much to do with the action and seem to give a sense of stimulation of relaxation, aside from any action that may be called tonic. Benefit has also been obtained in tabetic cases, also in spastic paraplegia where heat and pressure have been relied upon rather than greater degrees of cold. One patient with neuritis improved, another did not, while those with paralysis agitans have been better so far as general nutrition and a sense of well-being are concerned, but here there was a moderate amount of real gain. He believes that the education in an institute gives the patients ideas how to treat themselves at home, but he protests against the over-use of stimulation by friction in such treatment.

17.—This article appeared in *THE JOURNAL* of March 15, p. 683.

18. **Obliterative Pericarditis.**—After reporting cases and reviewing the literature Becker comes to the following conclusions: 1. Pseudo-cirrhosis of the liver due to pericardial adhesions is a distinct entity. 2. In all cases of this condition at autopsy the pericardial sac has been found obliterated. 3. Autopsies have shown in all recorded cases that the ascites is due to passive congestion of the liver, causing a connective tissue formation with subsequent contraction and obstruction of the portal circulation, the result of obliterative pericarditis. 4. In all cases of enlarged liver with ascites without edema or enlarged spleen, a very careful examination should be made of the heart to determine whether the symptoms are not due to chronic pericarditis. 5. The presence of ascites with enlarged liver and systolic retraction of the precordium together with absent or later appearance of edema of ankles is of great diagnostic value in determining the presence of chronic pericarditis.

19. **Cerebral Apoplexy.**—Fisher calls attention to the importance of alcohol and syphilis in the etiology of cerebral apoplexy and notices the symptoms, giving special attention to certain unusual forms. Among these he notices cases occurring in elderly persons where temporary paralysis occurred, which he explains by a stasis in the cerebral circulation, resulting in edema or what was formerly called serous apoplexy and other cases where the symptoms exist and yet no cerebral lesion is found, which he credits to a similar pathology. Epileptic seizures occurring in elderly persons and in those who have been free users of alcohol or have had syphilis are also traceable to this special condition. Pain followed by hemiplegia in the paralyzed members he believes is entirely cerebral or psychical. There is no reason why there should be pain as far as the peripheral nerve supply is concerned. He considers the Babinski reflex of value and says the best method to induce it is to use a sharp needle, scratching it first under the first metatarsal joint, and, if not successful, using it on the external side of the sole of the foot. As regards treatment, he would in ordinary attacks of cerebral apoplexy use free purgation and absolute rest, and administration of no drugs unless collapse shows itself. If the pulse is full and bounding, bleed through the veins, that is, administer aconite, but never use the lancet. If there is evidence of collapse with feeble pulse, administer digitalis or even strychnia and whisky. Such cases are usually due to thrombosis or embolus. As a rule, however, he favors doing little but giving absolute rest and meeting special contingencies as they occur. The most important time for treatment is in the prodromal stage when, if we have made out the etiologic factor, the indications are manifest.

21. **Antivenene.**—McFarland's review of this subject is apparently concluded in this issue and seems to be about as thorough a review of the literature as has been published.

22. **X-Ray Burns.**—The following are the conclusions of Codman's article: 1. The frequency of x-ray injuries has been much exaggerated by the medical press owing to the wide publicity given to many early cases. 2. The writer has been able to collect somewhat less than 200 cases, less than half of which were serious, and about one-third of which occurred in x-ray workers. 3. Judging from the experience with these injuries in Boston, it is the writer's opinion that a fair proportion of the severe burns are included in this series, while the dermatitis of skiagraphers is less well represented. 4. At a maximum estimate it is safe to say that not 1 patient in 1000 has been injured in the past five years by an x-ray examination and in the past year not 1 in 10,000. 5. More than two-thirds of these injuries occurred in the first two years of the use of the x-ray. Only one mild case is reported as occurring in the current year, those cases in which the exposure has been made for therapeutic purposes being excluded. 6. The cause of x-ray injuries is not definitely known. It is some form of energy closely allied to the photographically active x-ray and radiates with it from the platinum terminal. 7. The primary injury is to the nerves controlling the nutrition of the skin. 8. There is no good evidence of injury to the deeper tissues without primary interference with skin. 9. The important factors which contribute to the production of x-ray burns are: the intensity of the current used to stimulate the tube; the quality of the tube; the distance and time of exposure; the idiosyncrasy of the patient. 10. The static machine is somewhat less likely to produce injury than other forms of apparatus. 11. From the data of the reported cases we can say that no burn has been produced by an exposure equal to or less than the equivalent of 5 minutes at 10 inches. 12. It is impossible from the data to say how intense an exposure must be to produce a burn, for a comparison of the cases shows that an inconstant factor or factors exist. 13. These inconstant factors are more likely to lie in the complex human organism than in the less complicated construction of the tube. 14. General experience has shown that soft tubes produce a more intense effect on the tissues than hard. 15. While we can not control these inconstant factors, therapeutic exposures will continue to be dangerous, and it is therefore important to record the exact conditions of the patient's local and constitutional idiosyncrasies, as well as those of the tube. 16. In cases of injury the time before the appearance of the first symptoms has varied from a few minutes to three weeks. Five cases have remained latent for over three weeks, two of these for five months. 17. It is impossible to predict the severity of the lesion from the time of its appearance after exposure. 18. The writer suggests 10 minutes at 6 inches from the platinum terminal, as a standard therapeutic exposure. This will make comparisons between the inconstant factors easier. 19. Unless signs of dermatitis appear within three weeks after the exposure, they are unlikely to appear at all. In one-third of the reported cases the appearance occurred within the first four days; in one-half the cases before the ninth day. 20. In the ordinary x-ray examination with fluoroscope or skiagraph, the operator takes the entire responsibility of injury; in exposures for therapeutic purposes the patient shares the responsibility.

24. **Serotherapy in Epilepsy.**—Ceni concludes his article in this issue, reporting his last two cases. His researches demonstrate to him that in epileptic blood there are two active principles of different nature and origin. "One of these principles circulates in a free state and is only endowed with toxic properties when injected into the organism of another epileptic. The toxic effects may be immediate and direct and may follow even small doses. The activity of this toxic principle is different in different individuals. The phenomena it determines are transitory in character. The other active principle circulates in the blood of epileptics, but only in a latent state. It is endowed with properties which have a stimulating power on the metabolic cells which are concerned with the elaboration of the epileptogenous toxic agents. These stimulating properties

appear only as remote consequences that take place as a result of repeated injections over a considerable period of time, with the blood serum of an epileptic into himself or into another. These stimulating principles can deeply modify nutrition and epileptic manifestations. Upon both they exert a slow progressive action which may be restoring and therapeutic or weakening and poisonous. Their diverse and opposite modes of action depend upon some peculiar organic condition of the individual injected and are practically unexplained. The organic condition of the patient in whom they are elaborated has no apparent influence on the different and opposite activities they may present. In the cases in which stimulating principles have restoring therapeutic properties, there always result a remarkable increase in body-weight and an improvement or total disappearance of disturbances of organic functions or of social life. The disturbances of psychic functions and the epileptic manifestations of whatever nature get much better or disappear entirely. The stability of these positive results is in a direct relation with the degree of physiologic reaction in the elements of nutrition. In the cases in which the said principles do not act favorably on metabolism, the serum injections are useless. If continued in the same manner as in the preceding cases, there results a diminution in weight and a getting worse of every disturbance of the organic or social life. The psychic functions become more impaired and the epileptic manifestations increase in number and intensity, sometimes to a marked degree."

**27. Growth of Epithelium of Ulcers.**—Dentsch reports the results of experiments made to ascertain the rapidity with which new epithelium will grow over ulcers or raw wounds and to deduce from the results obtained methods by which the varieties can be quickly healed. The following is the summary given: "The observation of these cases has shown that 1, the rate of the growth of epithelium is in direct proportion to the size of the ulcer; 2, in the majority of cases the average growth of epithelium is from 2 to 3.5 mm. per week; the range is 1.4 to 10.5 mm. (traumatic ulcers not included); 3, the time required to heal an ulcer is in no proportion to the duration of the ulcer; an ulcer of 4 months' standing does not heal quicker than one of 4 years' standing, other conditions being equal; 4, the rate of growth of epithelium in traumatic ulcers is extremely irregular; it is in no relation to the size or duration of the ulcer; the average growth per week is about 5 mm.; the range is from 1.4 to 8 mm."

**28. Meat Preservatives.**—Vaughan and Veenboer have tested the effects of borax on the system and have looked into the literature on the subject, coming to the following conclusions: "1. The use of borax or boric acid as a preservative in butter and cream in the quantities specified in the recommendations of the English Commission is justified both by practical results and by scientific experimentation. 2. The dusting of the surfaces of hams and bacon, which are to be transported long distances, with borax or boric acid, not exceeding 1.5 per cent. of the weight of the meat, is effective and not objectionable from a sanitary standpoint. 3. Meat thus dusted with borax or boric acid does not become slimy because the preservative thus used prevents the growth of aerobic, peptonizing micro-organisms."

**29. Blood Examinations.**—Baldy questions the reliability of blood examinations as indication for surgical practice. He says that the leucocyte count can not be relied upon even to indicate with any degree of accuracy inflammation, to say nothing of pus formation, and has collected cases to demonstrate this statement. Moreover, the possibility that change in the blood count may be due to some complication altogether apart from a surgical condition should not be neglected. Pneumonia, for instance, is too common a complication of typhoid to be overlooked when leucocytosis appears as an indication of perforation. He does not wish to decri the value of laboratory work, for it has developed many valuable facts, but we are still far from having any positive value or aid from leucocytosis in surgical diagnosis.

**30. Sprue or Psilosis.**—The article by Musgrave is con-

tinued, and he reports cases with pathologic findings, clinical features and serum reactions. The usual bacillus found was the colon bacillus, though in 2 of the 16 cases the bacillus dysenteriae was also found. The latter is frequently difficult to find, although dysentery may be pronounced, in which it is the accepted etiologic factor. Streptococci were isolated in four cases and found in the stools in several others. Except the colon group, it is the pathogenic organism most commonly found. He concludes that sprue symptoms are nearly always found in the presence of other and well-known lesions, discoverable by careful clinical studies, aided by microscopic methods. Careful studies of these cases by modern methods may fail to indicate the additional etiologic factor. With our present knowledge it is more rational to consider sprue as a state or symptom-group (comparable to the typhoid state) occurring in the tropics in chronic diseases, especially those affecting the gastrointestinal canal.

**31. Urea Estimation.**—Behrend advises attention to diet in cases of urea estimation. The patient should be put on a special diet, rigidly enforced. Ordinarily this is not attended to and the urea estimation is made from small samples of urine, and is comparatively valueless. The patient must also be kept in a state of rest. Where the urea secretion is found very high or low and persisting so, we know that it is abnormal and usually associated with grave symptoms. Difficulty is only experienced when the estimation runs between 20 to 40, and when some defect in nitrogenous metabolism is suspected. He believes that with attention to these points the method is as close an approximation to the more exact methods as time and training of the general practitioner will permit.

**34. Rectal Diseases.**—Brav insists on the importance of digital examination in rectal diseases, maintaining that by it we can detect all pathologic changes occurring there excepting internal hemorrhoids. The internal opening of the fistula can be felt as a small pit or slight depression in the mucous membrane, generally more or less circular in shape, except when it originates from a tear by a foreign body or a detachment of a polypoid growth. Impacted feces and anal fissure frequently cause intestinal neuralgia and cystic neuralgia, and only digital exploration can reveal the true state of the case. Submucous abscesses are also thus to be detected. In making digital examination it is advisable to introduce the finger at first only as far as the distal joint, and to examine every portion within reach, gradually going further. Pathologic conditions close to the anus have often been overlooked by passing the finger at once to its full extent. On account of the importance of reflex symptoms from this part digital examination is imperative.

**39. The Biliary Flow.**—In a patient on whom he had operated, McLean tested the biliary flow, its amount, periods, etc. The tube was kept in the gall-bladder for ten days and over three quarts of bile were drawn without the least bad effect apparent on the patient. The digestion was perfect, appetite good and stools natural. He finds that the greatest amount of bile passes into the gall-bladder during the quiescent period; "that the administration of calomel and podophyllin will increase the flow; that the first two hours after a meal only one dram was passed into the gall-bladder; that the specific gravity varied from 1010 to 1014; no difference was noticed after the calomel was administered, and it was highest after taking solid food; that the gall-bladder will contain only a small percentage of the bile secreted during the quiescent period and is not a necessary appendage; that bile flows more freely into the gall-bladder the further down the small intestines the food products pass; that the secretion of bile is continuous and the entire amount secreted is not necessary for perfect health."

**50. Nargol.**—This is one of the more recently produced organic silver preparations, a chemical combination of nucleinic acid and metallic silver. It is a non-irritating, non-coagulable and non-caustic substitute for silver. It contains 10 per cent. of metallic silver as compared with 63.5 per cent. in silver nitrate and 8.3 per cent. in protargol. Schwarz has used

it extensively and made clinical comparisons with protargol in some 200 cases, nargol being used in one eye and protargol in the other under as nearly the same conditions as possible. His general conclusions are as follows: "Nargol is relatively non-irritating, has considerable range as an astringent, as well as superior penetrating power, stability, and solubility, and is most efficient in 10 to 20 per cent. solutions, which should not be kept more than five weeks. The addition of a few drops of a one-per-cent. chlorotone solution retards decomposition. In solutions of equal strength nargol is more stable and less irritating than protargol, and appears to be equally efficient."

**64. Gangrene of Lung.**—Packard and Le Conte's article contains a very elaborate description of a case, diagnosis and operation. Le Conte warns against opening a gangrenous cavity when adhesions of the pleural surfaces do not exist. The cavity should be emptied and examined to see if additional abscesses exist and these should be also looked after, but irrigation and curetting should be avoided. It should be wiped out simply with a gauze-guarded finger. The prognosis of these cases is almost always serious. The patient in this case finally succumbed to septicemia.

**70. Anesthesia.**—Dercum and Spiller's case of hemianesthesia of over eight years' duration seems to show in their opinion, "That organic hemianesthesia may be caused by a lesion in the *carrefour sensitif* and lenticular nucleus, without implication of the optic thalamus, except such as occurs from secondary degeneration. We emphasize the statement that in this case the inferior and external portions of the thalamus were intact. It seems to be the first case of the kind carefully studied in the literature. Whether or not the implication of the lenticular nucleus is necessary for the existence of organic hemianesthesia we can not determine by a study of our specimens. The integrity of almost the whole of the posterior limb of the internal capsule seems to indicate that the sensory fibers are located chiefly, if not entirely, in the area of the *carrefour sensitif*, or it may be that some sensory fibers pass through the lenticular nucleus. This view is in accord with the teaching of Edinger, inasmuch as he states that a portion of the sensory tract passes through the posterior third of the internal capsule and a portion through the lenticular nucleus. The lemniscus in its inter-olivary portion on the left side was one-fourth to one-fifth narrower than that on the right side and from this we conclude that the lemniscus on the left side had undergone retrograde atrophy. Some of its fibers, therefore, were probably cut in the lesion of the *carrefour sensitif* and lenticular nucleus."

**71. Diet in Chronic Heart Affections.**—Illoway shows that the stomach may exert an influence on the heart by the way of the vagus and mechanically by contiguity, and illustrates both of these actions by cases. The question of food, therefore, is of importance, and he says in regulating the diet for cardiopathies we must be guided by the well-established facts as to the nature of the various cardiac maladies and well-established facts of dietetics. In functional forms of heart disease all irritations of the stomach must be avoided. In organic conditions the mechanical influences also must be prevented. He therefore formulates certain rules: 1. All bulky and flatulent foods must be excluded, only foods that are readily and easily digestible allowed and all foods so cooked that their digestion is thereby facilitated. 2. All meals shall be small so that the stomach is not taxed too much nor greatly distended. The intervals between the meals must be so regulated that sufficient time is given the stomach to empty itself and to have an interval of rest before the next meal is taken. Diet tables are laid down by the author according to these rules.

**72. Sarcoma of the Pancreas.**—The difficulties of the anatomic conditions affecting the diagnosis of pancreatic disease are mentioned and a case reported by Käkels. In conclusion he says: The difficulties in the diagnosis of malignant pancreatic tumors are so numerous and great that we rarely find a case in literature where a correct diagnosis has been made before operation or necropsy. All or several of the symptoms (jaundice, ascites, pain, pressure symptoms, glycosuria, emaciation, etc.), together with the anamnesis, may lead to a prob-

able diagnosis. Recognition in the living of the nature of the growth is almost impossible. Tumors of the pancreas are of greatest interest to surgeons, as it has been only of recent years that operations have been made for their removal. For surgical intervention the most important symptom is a palpable tumor. Cysts have been incised and their contents evacuated. Less frequently, however, have solid growths offered opportunities for surgical interference. Removal of solid tumors with a portion of the gland itself is exceedingly dangerous and rarely successful. Even if it were possible to extirpate the gland, aside from the insurmountable difficulties on account of the blood vessels and close proximity of the neighboring organs, the surgeon would not be justified, because, as Minkowski has shown, the entire removal of the gland is followed by rapid and fatal diabetes.

**73. Urethral Discharge.**—Christian discusses the different forms of urethral discharge, their appearance, microscopically and macroscopically, causes, etc., and gives a table showing the differences between true gleet, prostaticorrhea and urethrorrhea.

**74. Sanitation After Floods.**—The sanitary conditions following extensive floods that have caused loss of life are noticed by Soper, who thinks the danger from decomposing animal and other matter is not so great as is usually supposed. The dangers of pestilence in these cases are not so much in the dead as in the living, among whom most insanitary conditions are likely to prevail. Sufferers from the flood should be aided and directed in their efforts to care for their own health. The causes of disease must be looked after, water supply and food inspected and damaged houses properly cleaned, aired and dried. Quicklime, chlorid of lime and carbolic acid will probably be the best agents, but bonfires should be made of all decomposing matter. He makes the special point that offensive or decomposing animal matter is not infectious and nausea is the most serious direct inconvenience to be caused by it.

76.—See abstract in THE JOURNAL, xxxvi, p. 1654.

77.—Ibid.

78.—Ibid.

**83. Thyroid Enlargement.**—Adami reports a case which is of interest on account of the rarity of the advanced condition of goiter enlargement affecting only the middle lobe and because of the symptoms to which it gave rise, viz., periodical attacks of dyspnea, which were mistaken for asthma and extended over eight years, and finally death from the same cause. The postmortem showed colloid or parenchymatous goiter of the middle lobe, the lateral lobes being atrophied and riding on the mass on either side above. He suggests that in districts where goiter is prevalent, as in the St. Lawrence Valley, periodical attacks of so-called asthma should be regarded as suspicious, the so-called cyanosis intensified by a certain amount of stridor should lead, in the absence of other explanation, to a careful examination of the lower portion of the neck.

**84. Foreign Bodies in the Appendix.**—From his study of the pathology, etc., of appendicitis, Stinson concludes that appendicitis is a surgical disease, the sooner operated upon the better. Early operation should give no mortality. In all appendicitis operations, the appendix should be removed unless irreparable damage is not done in the attempt. In local or general infection the abscess cavity or cavities should be thoroughly opened, all adhesions separated, all pus, shreds, etc., cleaned out, all inflammation of the pathologic omentum excised and all the infected portions of the abdomen thoroughly injected with hot water or hot saline solution and then dried with sponges. Fecal concretions are more apt to be present as the exciting cause of appendicitis than foreign bodies, though the latter are sometimes present. When, however, the appendix contains foreign bodies it is likely to be a pointed or a heavy body. Fecal concretions closely resemble some slight body like grape seeds or cherry stones, and a careful microscopic examination should be made to determine the exact nature. He believes operations such as those for appendicitis and other laparotomies can be as readily, safely and cheaply performed at the patient's home as elsewhere.

**89. Appendicitis.**—Cartledge believes in early operation, but if that is not possible, or the time is past, he thinks a patient living three days after the attack and not in hopeless general peritonitis has good prospects of recovery. We should be impressed with the idea that patients who die from acute appendicitis succumb, as a rule, within the first fifty hours of the disease. This paper was written because there are still general practitioners who believe that more cases of appendicitis recover without operation than with, and, second, because there are some surgeons who operate on every case of appendicitis seen, regardless of stage of disease or local or general conditions, excepting, of course, moribund cases. We take more risks in late operations than by the expectant plan. If the patient is still living and unoperated on at the end of three or four days, rest in bed, a light diet and administration of appropriate remedies will usually carry him over and the operation can be performed later. Cartledge long ago ceased to operate on general peritonitis cases; late operation is intended to prevent future attacks, early operation is intended to save the patient from the immediate attack. He rarely now operates on a condition of active adhesions and abscess. He would rather wait and take the chances of the adhesions melting down.

**90. Amputations.**—The method of amputation advocated by Vance is what he calls the modified circular antero-posterior flaps, for all operations. A few exceptions occur near the elbow and knee where some injury has so left the good tissue that to save the stump below the joint another method must necessarily be used. He describes the operation as follows: "An ordinary wide-bladed scalpel is held with handle at right angles to the axis of the limb and entered on the side, a little below the point of proposed bone section, cutting through skin and cellular tissue, parallel with the axis of the limb two inches, then across the limb in a slight curve, ending the incision opposite the starting-point. The ends of this incision represent the base of the anterior flap, which is dissected up. The posterior flap is made in the same way, but shorter, so that when they are brought together the line of closure will be back of bone or bones, as it may be. With the same small knife the muscles are divided circularly at right angles to the axis of the limb and on a vertical plane with proposed bone section, the flaps being held up by an assistant with two pairs of single-tooth forceps, care being taken not to incise the periosteum; with the same knife the interosseous space is divided half an inch below the point of proposed bone section and a long anterior periosteal flap is lifted, and held well up out of the way of the saw, which is introduced on a slant downward at an angle of 45 degrees, and the bone is divided for three-quarters of an inch and then re-entered vertically a little below the former point, both bones being completely divided. In this way the tibial crest is beveled before the limb is removed. Of course, when it is a thigh or arm amputation this is not called for. In a leg amputation the fibula is shortened three-fourths of an inch with the saw, slanting upward. It is my custom to use constant irrigation over the part while bones are being sawed to prevent possible heat necrosis. The vessels are carefully isolated and tied with plain catgut—No. 3 for femoral, No. 2 for tibial vessels. The nerves are drawn down and cut off square, three-quarters of an inch above the muscular section, the hemostatic bandage is removed, small vessels torsioned, oozing stopped by hot sponging with salt solution or by irrigation with same. The periosteal flap is sutured over the end of the bone by fine catgut. The flaps are accurately brought together by interrupted silkworm gut sutures, four or five being sufficient, then a continued fine suture of plain catgut closing perfectly the whole line of incision, except one-quarter inch at outer angle, where a short rubber drainage tube is introduced. A full aseptic dressing finishes the operation. At the end of 24 or 48 hours the drain is removed, and a second dressing applied, which is left on until the seventh day, when the silkworm gut sutures are removed and the stump is found firmly healed." The question as to where to amputate can be answered in a few words. The point of selection for the leg is 7 inches from the floor or 4 inches above the ankle joint. No operation between this

point and the mid-metatarsal region is surgical unless it is perfectly evident that an artificial limb can not be obtained. In all operations between this point and 4 inches below the base of the patella the old rule of save all you can should be followed. The point of selection above the knee is 3 inches above the patella. All operations between the site of the last-mentioned tibial and the first femoral are unsurgical without reserve. Above this point of selection the old rule of conservatism should be followed, excepting in malignant disease, when it is a question whether to do disarticulation in the hip, or leave sufficient bone for an artificial limb, and as a rule he does the latter. The question when to amputate is a little harder to answer. In most cases it is easy, but occasionally, difficult. If the surgeon thinks that there is a chance that the result of conservatism would be inferior to an artificial limb he should amputate, especially if he thinks the effort to save the limb is attended with greater risks. The patient frequently decides the question for him, but often disastrously. The difficulty then arises in cases of chronic bone disease of the ankle and knee. The chances of getting good results in conservatism in these is in proportion to the age. All malignant disease of the bones, joints or other parts call for amputation, excepting some of the skin cancers, the rules being to get well above the proximal point. Amputations for convenience are often indicated, the patient being more comfortable without the useless limb and with an artificial one. Frequently patients are thus converted from helpless cripples into useful members of society. In amputations of the hand or arm the rule of save all you can is to be followed, especially in laboring men.

**100. Tuberculosis.**—Bowditch gives his experience in Massachusetts with the sanatorium treatment of tuberculosis, showing that even in that climate with the unfavorable conditions presumed to exist in the region where the disease originated, it has been arrested in a progressively increasing proportion of cases. Of the incipient cases discharged during the past year in 79 per cent. it was arrested. Relapses seemed comparatively rare. Patients from the sanatorium going home distribute the acquired notions in regard to the hygiene of this disease and he gives a striking instance of this where a man, whose recovery excited the interest of his neighbors, began a crusade against the unhygienic methods which he found. Before long there was scarcely a family in the street where he lived that were not following his instructions.

**112. Pleurisy.**—Porter reports several cases of pleurisy, with purulent effusion, that show the accuracy with which most cases can be recognized, especially if the aspirating needle is used, but also how at times it is almost impossible for the best-trained diagnostician to be absolutely certain. They also show that diagnostic errors may have possible fatal results, especially if the most scientific methods of treatment are not adopted early. They also demonstrate the good results following resection of the rib and cleansing of the pus cavity. Small valvular openings do not give the same good results.

**113. Bronchitis.**—Love does not accept unconditionally the germ theory of bronchitis, but holds that changes of diet, disturbed digestion, constipation, perverted secretions and exposure to cold produce conditions which may be particularly favorable to the entrance of these organisms. We must bear in mind that the cause in the majority of cases has been the chilling of the surface of the body, which disturbs the circulation and causes stasis in various parts of the body, especially in the bronchial mucous membrane. We must not ignore the general torpor of the glandular system. As a rule, after investigating the case thoroughly we can use a purgative to get rid of the irritating matter and accumulated ptomaines. In further treatment he recommends the use of oil of turpentine on a lump of sugar given every two or three hours as one of the best stimulants of the glandular system. He would also use local applications of turpentine to the chest. The temperature should be watched, and if very high, cold baths are demanded. In children who can not expectorate, emetics will be required, as the secretion should be thrown off. He also advises stimula-

tion at proper times, giving one or two teaspoonfuls of whisky, glycerin, malt extract and honey. Another important step is the securing of rest, bearing in mind that we must not check secretion. To do this we must relieve the irritating cough. He has found heroin combined with ammonium hypophosphite, hyoscyamus, white pine bark, balsam, etc., excellent for this purpose. In making cough mixtures we should avoid syrups and we should not administer depressing remedies or those disturbing to the digestive tract. Sugar induces fermentation and disturbs digestion, which is against its use. We should also impress our patients with the importance of exercising their will power along with the medication to control cough.

**119. Eye Strain.**—Mills reports cases of headache due to eye strain relieved by operation. He thinks that headache from ocular defects are almost as frequently due to heterophoria as to refractive errors and that the former condition does not receive the attention it deserves. Imperfect equilibrium of the ocular muscles is not in most cases due to errors in refraction, though in the lowest degrees of the latter we find the highest degrees of the former, but before surgical procedure is adopted refractive errors, if they exist, should be relieved. Tenotomy should be employed only after a series of thorough and searching examinations.

**125. Angioneurotic Edema.**—Chisholm reports a case where the throat was involved and the conditions became alarming. Strychnin and nitroglycerin given hypodermically seemed to have no effect and he had resort to an atomizer with adrenal chlorid solution at full strength. In about two minutes the condition was markedly improved, respiration in five minutes becoming easy and natural. The eyelids and eyes were also affected and a drop or two was used there with pleasing effect. The patient was directed to swallow what remained in her mouth. The edema lessened very considerably over the body during the next two hours, itching was relieved and the face resumed its normal proportions, though there was still some slight traces of the tension that the parts had undergone. A slight return at night was relieved by the same treatment and another the next afternoon. This seems to have been the last return of the condition. The case seems worthy of notice on account of the usual unsatisfactory treatment in such cases.

**126. Suprapubic Lithotomy.**—The technique suggested by Chassaignac consists in the following principal features: "1. Introduction of stitches in a special manner to hold the bladder while it is incised and the calculus extracted. 2. Utilization of the same stitches in the closure of the bladder. 3. Formation of temporary drain by the collection of ends of catgut stitches. 4. Drainage by means of the Pezzer self-retaining catheter during the healing process." The details are given at length, but for lack of space can not be reproduced here. He thinks this method is of special advantage in cases where it is advisable to close the bladder completely, but it might be used on occasions where it may be thought best to close it only in part, using the two supporting threads as the limiting suture at each end.

**127. Antiseptic Dressing.**—The surgical dressing here recommended and described by Sharpe consists in a mixture of gum camphor and crystallized carbolic acid which, when triturated together, form a liquid having a pleasant camphoraceous odor. It is practically a local anesthetic and is, he says, the best all around antiseptic and aseptic dressing he has ever used. It is soluble in olive oil and for the after-dressings he generally used it in solution from 1 to 3 or 6 of olive oil. He finds this very soothing for burns, stimulates healthy granulation and is also a good local application in eczema, tetter, erysipelas, etc. It evaporates in the air, but the oil in the solution prevents this to some extent. He finds it of great value in ear inflammations; in short, there are few conditions of wounds in which it does not make good dressing. He makes no claims to the discovery of the compound; it is closely allied to a well-known proprietary remedy. His claims for it are that it is easily made, easily carried and a very effective antiseptic and aseptic dressing. It is not merely a surface remedy, but

penetrates into the diseased tissue. In conclusion, he remarks that as camphor and carbolic acid make such a non-toxic compound, the question arises whether the camphor would not be an antidote to carbolic acid poisoning. He has never used the preparation internally, but thinks it may be of value in some conditions as an internal antiseptic.

**130. Extra-Genital Chancres.**—The subject of innocent syphilis is discussed by Goltman, who notices some of the statements of authorities in regard to the matter and describes the principal avenues of infection. He thinks that the total abolition of syphilis would be impossible, but the innocent acquirement of the disease may be avoided without doubt and offers the following suggestions to this end: "1. Physicians should give their syphilitic patients explicit hygienic instructions, which would be better printed in booklet form. In my opinion a physician neglects a positive moral obligation if he fails in this. This, in my judgment, is the keynote of all prophylaxis, since all cases come under the physician's care sooner or later. 2. The habit of promiscuous kissing should be inveighed against—four of my five cases have been infected in this way—and much care should be exercised in the selection of servants, particularly nurses. 3. Barber-shops should be governed by proper legislation embracing a knowledge of the rudiments of the science of contagion, asepsis and antisepsis. 4. Physicians and dentists would do well to make examinations with more care and to perform minor and other operations with more deliberation. 5. The hygiene of industrial life should also be regulated. This would have a tendency to lessen other diseases besides syphilis, and could readily be done by disseminating the proper literature."

Titles marked with an asterisk (\*) are abstracted below.

British Medical Journal (London), March 8.

- 1 Two Cases of Spinal Cord Disease Consequent on Syphilis. T. R. Bradshaw.
- 2 \*Anatomy, Physiology and Pathology of the Imperfectly Descended Testis. W. McAdam Eccles.
- 3 \*The Influence of Phosphorus on Organic Substances in Pills. W. Harrison Martindale.
- 4 \*Luperal Insanity. Robert Jones.
- 5 A Case of Tumor of the Cerebral Cortex. H. Cecil Barlow.
- 6 \*The Results of Operation in 60 Cases of Malignant Disease of the Breast. A. Marmaduke Sheild.
- 7 The Blood Vessels of Mammals in Relation to Those of Man. F. G. Parsons.
- 8 \*A Contribution to the Study of Intestinal Sand, with Notes on a Case in Which It Was Passed. Dyce Duckworth and Archibald E. Garrod.
- 9 Some Experiments to Determine the Actual Efficacy of Izal Oil as an Intestinal Disinfectant. M. H. Gordon.
- 10 Two Cases of Lupus Vulgaris Successfully Treated with Urea Pura and the X-Rays. Edward Swales.
- 11 Abdominal Hysterectomy for Cancer of the Uterus. Robert O'Callaghan and Henri Dardenne.
- 12 \*Electric Shocks. F. B. Aspinall.

The Practitioner (London), March.

- 13 \*The Health of the People. James Cantlie.
- 14 Some Illustrations of Graves' Disease. G. A. Gibson.
- 15 Gout: Observations on Its Pathology, Forms, and Treatment. Arthur P. Luff.
- 16 \*On the Etiology of Pulmonary Tuberculosis. F. W. Burton Fanning.

Journal of Tropical Medicine (London), March 1.

- 17 \*Note on the Supposed Transmission of Plague by Fleas and Relapsing Fever by Bedbugs. George H. F. Nuttall.
- 18 Two Notes on Malarial Fever in China. W. G. K. Barnes.
- 19 Malarial Fever as Met with in the Great Lake Region of Central Africa. (Continued.) Albert Ruskin Cook.

2. Undescended Testis.—In these lectures, which are concluded in this issue, Eccles goes over all the abnormal conditions of undescended testis, including accidents which may occur from this cause and the effects on the development of the individual. He also considers morbid growths and teratomata; the latter he thinks may be an attempt on the part of Nature to produce a descendant from germinal epithelium that has remained from the primary genital mass, but undifferentiated, and this abortive development being without the help of the union of cells of the two sexes, results in the formation of the heterogeneous mass of sebaceous matter, teeth, ossifying cartilage, bone, hairs, etc. He has been unable to trace a record of true dermoid cyst of an imperfectly descended testis in the human subject, but there are several reported in animals. It is conceivable that the

testis, especially the imperfectly descended one, may contain the same or similar cells to those which the ovary does, and from which this curious growth takes its origin. The various forms of hernia connected with these conditions are also discussed.

**3. Phosphorus.**—On the suggestion of Sir William R. Gowers, Martindale has investigated the effect of phosphorus on alkaloids and other substances in pills, and finds that in most instances, in substances which were employed—strychnin, morphin, quinin sulphate, nitroglycerin and zinc valerianate in combination—there is no interaction or decomposition of substances associated with phosphorus. In zinc valerianate there was evidence of combination, but he is inclined to believe it has taken place in the process of extraction.

**4. Puerperal Insanity.**—Jones' paper discusses the statistics as regards this condition in some 3500 female patients, in whom he finds insanity connected with pregnancy, the puerperal state or lactation, in 259 cases, or 7.4 per cent. of the whole. Of this 259, 21.62 per cent. were cases of insanity during pregnancy; 46.33 per cent. occurred during the puerperal period, and 32.43 per cent. were associated with lactation. He is not inclined to think that there is any special type associated with either pregnancy or lactation, but the puerperal cases present such a marked delirium with wildness and delusions of a hallucinatory character in which religious and erotic features are so prominent that he recognizes it as an almost distinct nosologic entity. The statistics are carefully made and tabulated—the relation with illegitimacy, the form of insanity, the rapidity of onset, etc. The suicidal impulses were commonest in lactation cases and rarest in the puerperal ones. Most of the cases had undergone severe bodily strain, having had the care, responsibility, and management of homes under peculiar difficulties. Hallucinations of hearing were about six times as frequent as any other form, and he finds that marked sexual excitement was more frequently met with in this form of insanity than any other. The larger proportion, 73 per cent., of the puerperal cases consisted of first attacks. The onset of the insanity was apt to be sudden. Heredity occurred in nearly 50 per cent., and fully that percentage in the puerperal cases, while in the pregnant cases it occurred in 82 per cent. Of insanity among pregnant women a large proportion, 26 per cent., occurred among unmarried women, while these were rare as cases of insanity of lactation. In the strictly puerperal period, 12 per cent. occurred in single women. He thinks that during pregnancy the disgrace of illegitimacy exerts a great influence on the production of the condition.

**6. Mammary Cancer.**—Sheild claims the origin of the thorough operation for malignant disease of the breast for England, though he admits that Halsted has the credit of forcing it upon the attention of the profession. The effect of removal of the ovaries for malignant cancer is considered by him as unsettled and as yet in its experimental stage. He would consider three years as rather a short period to calculate a cure. In 60 cases operated on the operation was most thorough; all but two included removal of the axillary lymphatic tissue and every scrap of fascia. Where the axillary glands were infected also a part of the pectoral was removed. The skin has always been freely removed, so that in some cases he was not able to coapt it again after operation. The most striking general feature of his cases was the lack of local recurrences; if they did occur they would be only small or of a nodulous nature and easily removed. In 40 tabulated cases, 8 patients were well for five years, going on six, 4 for four years and upward, 7 for three years and upward and 11 for two years. In the cases that showed local return within two years a second and slight operation has given them a fresh period of freedom from the disease. In conclusion he says the following lessons seem to be inculcated from the faithful record of these 60 cases: "1. That the risk of removing cancer of the mammary by extensive operation is small and should not amount to more than 1 or 2 per cent. Sepsis is preventable, and when it occurs it is a blameworthy error on the part of the surgeon. 2. That

early and free removal gives prospect of years of freedom and in a good percentage of cases of good health and enjoyment of life. 3. That the cases which do badly are (1) soft, rapidly growing cancer in young and vascular women, and (2) cancers of long continuance before operation where the skin and cervical glands are widely infected. 4. That in certain cases visceral cancers and cancers in the liver co-exist with or rapidly follow operation, and the explanation of these is uncertain. 5. That the practice of early exploration by incision of small nodules and indurations in the breast is of the first importance and should be strongly urged upon the profession generally, especially upon those in general practice who so often see these cases in their early beginnings and on whom the great responsibility of prompt diagnosis falls. 6. No one should undertake an operation for mammary cancer unless he is capable, and has had sufficient operative experience, to remove thoroughly all lymphoid tissues from the axilla, the leaving of infected glands towards the apices of the axillary spaces being a common source of failure in the results of this operation. 7. The prognosis of mammary cancer is still dubious and sometimes instances arise which falsify ordinary experience. Bad cases have long freedom from return. Early cases show recurrence. But such do not invalidate the rule: Operate early, operate extensively."

**8. Intestinal Sand.**—This subject has apparently received little attention from the English-speaking profession, though considerable has been written on it by Continental writers. Duckworth and Garrod report cases, with examination of the material, including spectroscopic examination. They classify the varieties of intestinal sand into two groups: 1. False intestinal sand composed of vegetable remains that resist the action of digestive fluids and may or may not have acquired some incrustation of earthy salts. 2. True intestinal sand, which has no special vegetable basis, and owes its hardness and grittiness to inorganic material which it contains. The organic basis of this is of animal origin and the authors are inclined to think it originates in the intestines, chemical and clinical evidence both alike pointing in this direction. The nature of the pigments suggests the colon as the most likely seat for the formation and the anatomic structure of the large bowel may be looked upon as more favorable than that of the small intestine to the sojourn required for the deposition of the earthy salts of which the material is so largely composed.

**12. Electric Shocks.**—This paper, read before the Institute of Electrical Engineers by a layman, contains many interesting points. He discusses the following questions: 1. Is everyone equally susceptible to an electric shock? He holds there is no absolute proof as to this. His own opinion is that not only different people are differently affected, but the same persons under different conditions do not feel the same effects. 2. Is a person suffering from disease more likely to be fatally injured by an electric shock than a person in good health? He finds that apparently a low grade of intellect seems to favor insensibility to electricity. The brain does not so quickly react. He has also observed persons suffering from kidney disease to be specially sensitive. This seems to indicate that the resistance of the body may be altered by disease. As regards the question, whether the physiologic condition at the time shock is received make any difference, he quotes cases that seem to show that free perspiration seemed to shunt off the electricity, making the matter much less serious than would otherwise be the case. Also, drunken people seem to be less likely to fatal accidents, though the evidence is not very strong; similarly, people that are asleep. He arranged once for his assistant to give him a shock when he was in bed asleep, and though two witnesses guaranteed the assistant had done so, he felt nothing. In one case a man who was stationed to watch a cable carrying 5000 volts, went to sleep and fell upon it. He was most severely burned, but was not killed. Aspinall seems to think that the passage which the current takes through the body has an effect as regards fatality, and that the left side is more vulnerable than the right, and gives evidences. He believes the reason is that the valves of the heart on that side

are more easily damaged. The amount of contact and the effect of burning as having an influence on the fatality of the shock, is discussed. He thinks that a person could probably kill himself with a smaller voltage with large contact. Burns, he thinks, may have a good effect, increasing the resistance. In most of the cases he noticed the fatal effects were where the burns were slight. His opinion is that moistness of the skin reduces the chance of burning, as it insures better contact; if no burning takes place efforts to help the victim should be redoubled, when it is thought he has received a shock, though severe burning may occur after a sufficient current to kill has been received. He is also inclined to think that the fatal shock may not destroy consciousness and the person be able to speak before he succumbs; he reports a case indicating this. The peculiar cry which usually attends the severe electric shock is not absolutely invariable, as in one instance he did not observe it. As regards the effect of the alternating and direct currents he is rather inclined to think the direct current possibly a little more fatal. It will much more quickly break down any fault in conduction than the alternating current, but if otherwise the conditions are the same both currents will kill a man equally well. If death occurs from an electric shock both are equally dangerous; if death occurs from burns, the direct current is worse; while burns themselves are protections in his opinion, they may yet be severe enough to cause death. As regards the actual voltage required to cause death he would say that "at below 600 volts the conditions must be abnormally favorable; at below 1000 volts they must be favorable; and at above 1000 volts, the higher the pressure the more easy it is to get the conditions necessary to cause death." On the whole there is really not much more danger in one system than another; it is purely a question of voltage. He asks if medical men can not give us more certain methods of ascertaining whether a man is dead or not from an electric shock; the lack of this is unfortunate, and he inquires if anything more can be done to help people that have received shocks. He wants to know what it is that breaks down when the shock is received. Is it the lungs, the heart, the blood, or the brain? Electricity, in his opinion, acts somewhat as an anesthetic like chloroform, and he has seen two cases where death was expected, but where the men recovered from the head being lowered, thus flushing the brain with the blood as is done in cases of chloroform asphyxia. He asks: Should we adopt the same treatment before applying artificial respiration, namely, hold the body a few seconds head downward?

**13. The Health of the People.**—Cantlie discusses the sanitary condition of the British population, showing how the race is degenerating, under conditions of town life, with its bad air, lack of exercise, etc., its bad effect on children and young adults, and the diminished effect of the church in cities as compared with country. He discusses the physique of boys and girls. While he admits that the girls of the middle classes are improving, this is not true of the masses, and it is not even true of the boys of the middle class. The present system of dress and bringing up is damaging in the case of boys. He is inclined to conditionally endorse Kipling's criticism of English games. He believes they are carried over to adult age to an unreasonable extent. The remedies which he sees for the degenerative influences on young men are compulsory military service, which he believes would have a generally beneficial effect, and improving the condition of agricultural labor, thus making country life more attractive.

**16. The Etiology of Pulmonary Tuberculosis.**—Burton Fanning holds that consumption is communicated to individuals at different periods long before it has an outbreak, yet it forms a lodgment, lies latent in the system to be later aroused and developed. He thinks at least 40 or 50 per cent. of people carry in them germs of this disorder, which may break out, and that a large class of people, who are considered naturally delicate but free from organic disease, are really suffering from masked tuberculosis. He attributes considerable importance to heredity. In 54 per cent. of his own cases there is a family history of pulmonary tuberculosis. There are a number of conditions which tend to bring out this disorder, among

them being influenza, malaria, dysentery and measles. A strikingly large number of his consumptive patients have been martyrs to migraine. A man with a tubercular focus ought not to take any liberties with his health or overstrain himself. In 10 per cent. of his cases the author attributes the occurrence of manifest tuberculosis to overfatigue, overindulgence in athletics, dancing, climbing and games. He does not touch upon the subject of overcrowding, close confinement or bad air, which are specially active in producing tuberculosis of the poor.

**17. Plague.**—Nuttall notices Galli-Valerio's article (in a previous abstract) in regard to the transmission of plague by fleas and refers to his own experiments as having the same bearing. He finds that the bacilli are largely digested by insects and therefore not likely to do so much harm, at least if transmission does not occur immediately. He has experimented not only with fleas but with flies and bedbugs and would suggest that experiments be tried on a suitable species of monkey. Bedbugs are easy insects to work with. They can be kept without food or water for several months and in this condition will bite immediately.

**21. Chloroform in Heart Disease.**—Guyon remarked that he had frequently had occasion to operate on subjects between 60 and 90 years of age, and once on a man of 91. Atheromatosis and heart affections are not rare at these ages, but the chloroform was perfectly tolerated. He even noted in a number of cases that the heart action seemed to have been permanently benefited, confirming Hare's experience. He has lost two patients under operation and in both the heart was in fatty degeneration, hence he warns against this condition, but affirms on the other hand, that chloroform can be administered to patients even when they are known to have exhibited symptoms of atheroma or angina pectoris. He thinks it is possible to avert syncope, even in extreme anemia, by the Trendelenburg position. He has had no fatalities since this was introduced. The pulse must be watched as carefully as the respiration, especially during the third stage of chloroform. Brouardel stated that he had served as medical expert in twenty-five cases of sudden death under chloroform. One was a child with an enlarged thymus and one a woman who succumbed to pulmonary embolism after reduction of a fracture of the femur. None had any evidences of a valvular defect, but in three the heart was loaded with fat, although the cardiac muscle was not altered. In one patient the heart was in actual fatty degeneration, but the patient died in reality from congestion of the lungs. The subjects were between 13 and 52 years of age, the 9 men all under 47. In 14 cases the operation had not commenced; in 3 it had just commenced, and in the case of fatty degeneration mentioned above, death occurred after a luxation of the femur had been reduced, a minute or two after cessation of the chloroform. Death was attributed by the surgeons in all these cases, except one, to a cardio-pulmonary syncope. Renal lesions were frequent in the various subjects. In one woman the kidney was enormous on one side and a mere calcareous lump, weighing 6 gm., on the other. He does not incriminate these renal lesions in the causation of the chloroform fatality. From the medico-legal standpoint, the latter can be compared only to the sudden deaths which occur from blows in the region of the larynx, sometimes very slight injuries. Brown-Séquard described these fatalities as "inhibition phenomena," irritation of the laryngeal region entailing abrupt arrest of respiration and circulation. In addition to traumas of this kind, so trifling that they leave no trace on the cadaver, the same accidents have been observed from mere excitation of the nasal, pharyngeal and laryngeal mucosa. He cited a case of sudden death during sneezing, and 2 cases during a mild catarrhal sore throat with no trace of edema. Both were young men, one a medical student. Any lively excitation of the superior laryngeal nerves, the terminal ramifications of the trigeminal, is liable therefore to induce the cardio-pulmonary syncope or death from inhibition. Sudden death just before or during a surgical operation was known before the discovery of chloroform. He quoted examples of such occurrences reported by Lisfranc, Desault, Simpson and others. The

use of anesthetics did not create a new kind of death from stoppage of heart and lung action. The danger is not exclusively in the administration of the anesthetic agent; it lies also in the innate or acquired susceptibility of the patient. The chloroform causes the explosion of this hitherto latent disposition. He does not believe that it is possible to detect this susceptibility beforehand as a general rule, but occasionally the antecedents may afford a hint. An emotion or excitement which would not affect a healthy person, assumes intense proportions in debilitated, cachectic subjects. The regions innervated by the terminal branches of the trigeminal, by the superior and inferior laryngeal nerves, are especially liable to induce this arrest of the respiration and circulation under the influence of sometimes merely slight stimuli or impressions. Anesthetics which act by penetration of their fumes into the pharynx and larynx, across these nerves, have a direct stimulating action on these peculiarly excitable regions and may arouse a heretofore unsuspected susceptibility. The mode of administration of anesthetics is therefore not the only factor to be invoked in case of an accident. The personality of the subject, his special susceptibility, are frequently the principal causes of death.

**22. Sodium Methylarsinate.**—Gautier's success with cacodylic medication inspired him to seek for a still more effective means of administering arsenic. He finds that the sodium methylarsinate (methylarsinate disodique), or arrhenal, is even more effective than the cacodylates, while it has the advantage that it can be administered by the mouth without by-effects, even from prolonged use, with intermissions every four or five days. It increases the appetite, restores the strength, raises the arterial tension and causes a marked increase in the number of red corpuscles and of the large mononuclear cells. He reports in this communication the results of its administration by himself and his colleagues in tuberculosis, chorea, uncontrollable vomiting, pernicious anemia, malaria and cutaneous affections. The average dose is 10 cg. a day. The name arrhenal is derived from the Greek term for arsenic.

**23. Placenta Previa.**—Vézina describes four cases of placenta previa and recommends his practice of first administering half a dram of fluid extract of ergot in such cases. Then, when dilatation is sufficient he practices version if necessary and extracts the fetus. He gives no anesthetic and relies exclusively on the ergot and tamponing, which supplement each other. The patients all recovered, with the death of one fetus.

**25. Association of Pupil Disturbances with Lesions of the Aorta.**—The pupil disturbances observed in case of a lesion of the aorta are attributed by Babinski not to a mechanical cause but to the action of the same poison in the system that is inducing the aortic affection. Vaquez reports three cases which confirm this view and demonstrate its importance in pathology. In one of his cases, the aortic valvular lesions and the loss of the pupil reflexes were the only signs of syphilitic infection. Their coincidence should always suggest the possibility of syphilis, and the pupils should always be examined in case of aortic lesions.

**26. Lead in the Viscera in Lead Poisoning.**—Launois has a special apparatus for reduction and electrolysis of the tissues to be examined. He found deposits of lead in the brain in 8 out of 10 cadavers examined, and only once in the spleen or lung.

**28. Ascending Neuritis in the Etiology of Syringomyelia.**—Guillain describes the case of a man of 50 who developed a large phlegmon in the palm consecutive to a trifling injury. As the phlegmon healed symptoms of ascending neuritis from the injured point became apparent and gradually progressed into pronounced syringomyelia, of which the patient is now a typical example, twenty years after his primary phlegmon. Marie, Eulenburg and Schlesinger have each described a similar case consecutive to a phlegmon on the hand or in the axilla. The infection evidently reached the spine by way of the nerves, which may also occur in case of tetanus and hydrophobia. It is possible that certain suppurations noted

in the course of syringomyelia may be primary instead of a casual coincidence or secondary. Certain puzzling affections of the spinal cord, medulla and pons may be due to infectious or toxic agents arriving from the periphery by way of the nerves.

**29. Relief of Syphilitic Cephalalgia by Lumbar Puncture.**—This communication from Fournier's service describes the great benefit derived in several cases of syphilitic cephalalgia by lumbar puncture and withdrawal of a small amount of fluid. The results seem to indicate that the cephalalgia is in reality a meningitic symptom revealing hypertension of cerebro-spinal fluid.

**39. Radioscopic Diagnosis of Sclerosis of the Interlobar Pleura.**—Béclère asserts that it is possible to diagnose the condition of the interlobar pleura by radioscopy. The latter is not complete until the thorax has been inspected from the front, from the back, from the side and obliquely, with the tube held in each of these positions at various heights from the top of the head to the inferior strait of the pelvis. He points out that a sheet of cardboard is permeable for the rays when inspected from the front or back, but that it casts a dense shadow when the edge alone is presented to the tube and the rays have to pass through its entire length. In the same way, the pleural partition that separates the upper lobe of the lung from the middle and lower lobes, casts no shadow unless the rays pass through its entire length and not even then unless in case of fibrous thickening, which is possible to be diagnosed with certainty.

**45. Restoration of Defect in Nostril.**—Koenig successfully substituted a missing portion of the nostril by a corresponding piece of tissue cut out of the upper portion of the ear. The patient was a girl and the defect in the ear could be easily concealed by the hair. It is seldom that the surgeon is able to supply a defect with such a perfect substitute as the flap in this case, almost identical in structure on both sides, and with the free edge apparently continuous with the edge of the intact nostril. In case the flap should show signs of necrosis, he has the other ear for another attempt.

**54. Brookes' Paste in Inflammatory and Infectious Cutaneous Affections.**—Dreyer attributes the great efficacy of this paste to the combination of the three important disinfectants, salicylic acid, ichthyol and mercury in the very soluble form of the oleate. The formula is as follows: Hydrargyr. oleicæ, (5 per cent.), 28; zinc oxid and amyli, 55 7; vaselin alb., 14; ichthyol, 1 to 2; acid. salicyl., 1.2 to 1.8, and ol. lavand. qu. sat. He describes his experiences with it and mentions among other instances of its efficacy a case of gummatous ulceration of the ear which had persisted for several years, notwithstanding inunction treatment. It healed in two weeks under the paste and injections of mercury salicylate. The paste must be smeared over the spot and covered with cotton. It is not effective when applied on a rag. Inflamed hemorrhoids, syccosis, eczematous erosions, soft chancre, etc., afforded equally favorable results.

**56. Cancer in the German Empire.**—Wutzdorff gives numerous tables and charts showing the distribution of cancer in the different parts of the empire as compiled by the imperial council of health. They show that the number of cases of cancer has materially increased since 1892, the proportion of increase surpassing that of the population. The age of the subjects averages younger than in former years. Women are more frequently affected than men, but do not succumb to the cancer in as large a proportion. Cancer is most prevalent in the Lübeck and Hamburg districts and is increasing most rapidly in the latter and in Wurttemberg. The southern provinces of the empire are the least affected.

**58. Tonic Contraction of the Stomach.**—Boas describes a contraction of the anterior stomach wall similar to the phenomenon called "stiffening of the intestines" by Nothnagel (Darmsteifung). It is the early phase of Kussmaul's "peristaltic restlessness of the stomach." Boas has been studying this "stiffening of the stomach" for several years, and states that it is a comparatively frequent and in certain instances an extremely important diagnostic sign. It may be slight, restricted

to a small portion of the fundus, and palpable as merely exaggerated tonic of the gastric musculature, subsiding after a few seconds. These abortive contractions do not seem to be felt by the patient and are not associated with any perceptible noise. The contractions may occur more distinctly, and be palpated as a marked increase in the tonus, visible as a protuberance of a larger or smaller portion of the wall of the stomach, and terminating in a perceptible gurgle as the contents are forcibly expelled. These contractions are slightly painful. In other cases the contractions may be very vigorous, lifting up portions of the stomach above the level of the abdomen and lasting some time, terminating with a loud gurgling noise and causing more or less decided pain. In 5 cases of spasmodic contraction of the pylorus this stiffening of the stomach was a prominent symptom. It was also pronounced in cases of organic stenosis of the pylorus on a cicatricial or carcinomatous basis. He relates several case-reports as typical specimens of the phenomenon and proclaims that it can be accepted as the precursor of visible and palpable gastric tetany from impermeability of the pylorus. It is the first sign of some interference with the permeability of the pylorus, while it can still be overcome. When the obstacle becomes unsurmountable, the hitherto regular although exaggerated tonus becomes irregular and spasmodic. The tonus becomes tetany. The obstacle to the permeability of the pylorus may be purely functional or organic, either cicatricial or due to a neoplasm in or near the pylorus or to displacement. The stiffening is valuable as a differentiating measure against atony of the stomach and gastric myasthenia. It establishes the existence of some obstacle at the pylorus in cases in which all the symptoms indicate atony. When the diet is regulated and the stomach duly rinsed, it is almost impossible to detect this sign except when the stomach is full, at the height of digestion, that is, three or four hours after dinner. Rubbing the fundus with the hand dipped in cold water or after ether has been applied or after Faradization, are useful adjuvant factors in its production. The diagnosis is much facilitated by this sign of incipient stenosis of the pylorus. As internal treatment is rarely successful in such cases, it will stimulate the patient to accept surgical intervention at a time when otherwise the symptoms do not positively indicate it. Boas does not advocate operating for mere spastic stenosis of the pylorus, as internal treatment is preferable for the majority of such cases, along the lines of internal treatment of the so-called mechanical insufficiency of the first degree.

**60. Paralysis of the Organs of Sense After Pertussis.**—The child in the case described became blind, deaf and dumb in the course of a severe attack of whooping cough. The behavior of the pupil reflex in this and a case described by Alexander indicated that the disturbances were due to pathologic alteration of the nerve centers, probably from edema of the brain. There was no albuminuria. One of the three cases on record died, both of the others recovered.

**64. Modification of Biologic Blood Test.**—Mertens points out that the rabbits are injected in the peritoneum by the Hungarian, Uhlenhuth, and subcutaneously by the Germans, Wassermann and Schütze, to obtain prepared serum for the biologic serum differentiating test of blood. Experience has confirmed the great value and reliability of the test, but he finds that it can be simplified by making the injections into the veins of the animals. The serum thus prepared has proved 150 times as powerful in some of his experiments, while the diagnosis is possible in one hour instead of in twenty-four by the peritoneal method. The intravenous method is also preferable for the reason that bacteria in the fluid injected soon die in the animals' blood. The rabbits also tolerate intravenous injections much better and they can thus be repeated oftener. He mentions with approval Ziemke's method of extracting the blood stains with a concentrated solution of potassium cyanid. The extract is then shaken up with a few scraps of tartaric acid and tested constantly with red and blue litmus paper until a neutral reaction is almost reached. The resulting fluid is limpid when still slightly alkaline, but remains turbid as long

as there is a trace of acid in excess. It is then diluted with water to a laky tint and is then ready for the serum test. A scrap from the stomach of a cadaver that had been buried ten years reacted positively to the test thus modified.

**65. Fatal Hemorrhage After Tonsillotomy.**—Damianos states that about 150 cases of severe hemorrhage after tonsillotomy are on record, only seven of which proved fatal. He had occasion recently to observe another fatal case, distinguished further by the formation of a gas abscess after a subcutaneous injection of gelatin. The patient was a young man with a tendency to hemophilia. When the tonsil was removed the incision passed through the plane of the outer capsule of the tonsil where the trunks of the tonsillar arteries pass before ramifying. The side wall of one of these arteries had been injured by the operation, and its intimate connection with the fibrous capsule impeded its contraction and retraction, thus interfering with hemostasis. He therefore warns against the complete ablation of the tonsil. It is entirely unnecessary to remove all of it, while the case described shows the dangers of such a procedure. In the partial removal of the tonsil only small ramifications of the tonsillar arteries can be injured, and the yielding structure of the remaining portion of the tonsil left allows of contraction and retraction. The hemorrhages followed the use of the knife, of the tonsillotome and even of the thermocautery. In some of the cases it occurred at once and in others appeared or recurred several days later. The hemorrhage ceased in a few cases as the patient fainted, and in others the fainting was artificially induced as a last resort by raising the patient to a sitting posture, with the same success. Hood noticed that the hemorrhage ceased as the patient vomited in one case, and he arrested the hemorrhage in another patient by administering an emetic. Others were successful in arresting the hemorrhage by applying an astringent. Hovell uses a paste of one part gallic and three parts tannic acid mixed with a little water and rubbed with the finger into the bleeding spot. Several report arrest of the hemorrhage under ergotin, others after cauterizing with the thermocautery. Panas advocates digital compression as the most effective measure, kept up possibly as long as two hours. The bleeding artery has been twisted or ligated in some cases and the carotid artery has been compressed or ligated in others. The last resort seems to be ligature of the external carotid or of the common carotid artery. About six cases have been treated by the latter method. Three of the seven fatal cases were after operations by charlatans. Another was a rebellious child whose screaming detached the thrombus which had arrested the bleeding at first. Another patient was a girl of 13 who made a sudden movement to stand up andretch during the operation on the second tonsil. The first had been successfully removed. The knife slipped and severed a small artery and vein in an incision .5 cm. deep beyond the tonsil. The death was ascribed to penetration of blood into the air passages, but the operator, Schuchardt, held to the opinion that the circumstances of the case justified the assumption of shock, as the patient fainted and died after gasping twice.

**66. Typhoid Bacilli in the Sputa in Typhoid Fever.**—Jehle examined the sputum from 23 cases of typhoid fever and cultures were made from the bronchial secretions in 15 cases that came to the autopsy. He found that the sputum had a marked hemorrhagic character in the cases complicated by pneumonic infiltration, and that it frequently contained typhoid bacilli alone or associated with other microbes, especially the influenza bacillus. He also succeeded in determining the presence of typhoid bacilli in the sputum in the cases of clinically and anatomically uncomplicated bronchitis. The importance of this last fact is apparent for the prophylaxis of typhoid fever. One of the cadavers displayed a recent hemorrhagic pneumonia while the typhoid lesions in the intestines had evidently been long healed. Typhoid bacilli were numerous in the sputa. In another, a fatal suppurative cholangitis had developed after two months of undisturbed convalescence from typhoid fever; pure cultures of typhoid bacilli were derived not only from the biliary abscess but from the lung juice in this case; also from

4 out of 5 cases of pronounced pneumonia and in 2 out of 6 cases of uncomplicated bronchitis in typhoid fever. The findings in one cadaver suggested that the typhoid hemorrhagic lobular pneumonia and pleuritis were the primary affections, as no lesions were discoverable in the intestines. The mesenteric glands, however, and the intestinal mucosa contained the bacilli in large numbers.

**68. Bloodless Treatment of Muscular Torticollis in Children.**—Lorenz describes the fine results attained by subcutaneous intentional rupture of the sterno-cleido-mastoid muscle to cure obstinate wry-neck in children. The subject lies with a hard cushion under the shoulders, the head and neck unsupported. The shoulder is drawn down at the same time and it is thus possible to tear the muscle by gradual dehiscence, followed by over-correction. Parents accept this operation much more readily than when the knife is used, and the dehiscent fibers heal under the intact skin with little if any cicatricial formation. The cure has been ideal and permanent in all his cases.

**77. Per-Oral Intubation.**—Krug reports twenty-two cases in which Kuhn's per-oral tube was applied, with success surpassing all anticipations. See THE JOURNAL of January 25, p. 284.

**79. Reaction to Tuberculin in Convalescents from Pleurisy.**—The tuberculin test proved positive in fourteen convalescents from serofibrinous pleurisy free from any clinical signs of tuberculosis. Romani thinks that the reaction must have been due to some small latent focus escaping all our means of research except the tuberculin test. He ascribes the pleurisy in such cases to infection from these latent foci. The germs pass by way of the lymph to the pleura and there set up inflammation that may remain limited to the pleura and not involve the primary focus, which remains latent. Every pleurisy which can not be traced to some other known process may be assumed to be secondary to a tubercular focus whether it is apparent or not.

**80. Susceptibility of Insects to Tuberculous and Diphtheric Toxins.**—Centanni noticed that the larvæ of house flies usually refused to feed on the flesh of animals that had been used for laboratory research, or if they did feed on it, they soon died. He therefore instituted experiments which proved that maggots and similar insects offer most interesting and demonstrative material for research on the action of bacteria and their toxins. He found, for instance, that the tubercle bacilli ingested by the maggots did not penetrate into the tissues, but evidently killed the insects by their toxins. If only a small quantity of bacteria were ingested, they were eliminated *en masse* without apparent injury to the maggot. After ingestion of a small amount of diphtheria bacilli on the other hand, the epithelium of the intestines shows specific alterations, but it seems to acquire a kind of immunity, as there is no further absorption and the bacteria and their toxins can remain in large quantities in the intestines without harm to the insect until their final expulsion. The simplicity of the construction and of the vital processes in insects renders them peculiarly instructive for such research.

**85. Treatment of Oriental Sore with Finsen's Phototherapy.**—Petersen remarks that an oriental sore is easily diagnosed when it is encountered in the places where it is endemic, but may prove puzzling when first observed at St. Petersburg for example. He has recently had two such cases. One was at first assumed to be a gummatous ulcer as the patient's statement that she had recently arrived from the Orient was unheeded. It healed in the course of four months under curetting and iodine. The second patient was an actress from Turkestan, and the ulcer involved the nose and part of the cheek. Under Finsen's phototherapy the lesion healed with the minimum of scar formation. The effect in this case was so striking and the treatment seems so rational in these evidently parasitic lesions, that Petersen and Finsen, with whom he corresponded on the subject, now recommend phototherapy as eminently adapted for the treatment of endemic oriental sores. The sun's rays can be utilized in the tropics without the expensive electric light apparatus.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**DISEASES OF THE INTESTINES.** Their Special Pathology, Diagnosis, and Treatment. With Sections on Anatomy and Physiology, Microscopic and Chemie Examination of the Intestinal Contents, Secretions, Feces and Urine: Intestinal Bacteria and Parasites; Surgery of the Intestines; Dietetics; Diseases of the Rectum, etc. By John C. Hemmeter, M.D., Ph.D., Professor in the Medical Department of the University of Maryland. In Two Volumes. Vol. II: Appendicitis, Tuberculosis, Syphilis, Actinomyces of Intestine, Occlusions, Contusions, Rupture, Enterorrhagia, Intestinal Surgery, Atrophy, Abnormalities of Form and Position, Thrombosis, Embolism, Amyloidosis, Neuroses of the Intestines, Intestinal Parasites, Diseases of Rectum. With Plates and Many Other Illustrations. Octavo. 675 Pages. Price, Vol. II, net, \$5.00. Philadelphia: P. Blakiston's Son & Co. 1902.

**PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN.** A Series of Eighty Plates, Comprising More Than 100 Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics. By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York. Price, \$1.50 each. Part IX. Paper. Philadelphia and London: J. B. Lippincott Co. 1901.

**DISEASES OF WOMEN: A Manual of Gynecology Designed Especially for the Use of Students and General Practitioners.** By F. H. Davenport, A.B., M.D., Assistant Professor in Gynecology, Harvard Medical School. Fourth Edition, Revised and Enlarged, with 154 Illustrations. Cloth. Pp. 402. Price, \$1.75. Philadelphia and New York: Lea Brothers & Co. 1902.

**OBSCURE DISEASES OF THE URETHRA.** By E. Hurry Fenwick, F.R.C.S. Eng., Surgeon to the London Hospital. With Special Chapters on Urethral Carcinoma and Calculus, by J. W. Thomson Walker, M.B. Edin., F.R.C.S. Eng. Cloth. Pp. 154. Price, \$2.60 net. Philadelphia: P. Blakiston's Son & Co. 1902.

**COURSE OF GENERAL PATHOLOGY.** By Alfred Edward Thayer, M.D., Assistant Instructor in Gross Pathology, Cornell Medical College. Containing 78 Illustrations, Several of Which are in Colors. Cloth. Pp. 321. Price, \$0.80. Philadelphia: P. Blakiston's Son & Co. 1902.

**PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION at the 49th Annual Meeting, Held at St. Louis, Mo., September, 1901, also the Constitution, By-laws and Roll of Members.** Cloth. Pp. 1028. Baltimore: Published by the American Pharmaceutical Association. 1901.

**REPORT OF THE VITAL STATISTICS OF THE CITY OF HAVANA, Made to Brigadier General Leonard Wood, U. S. A., Military Governor. Year, 1901.** By Major W. C. Gorgas, Surgeon, U. S. A., Chief Sanitary Officer. Paper. Havana: Avisador Commercial Printing Office.

**PSYCHOLOGY, Normal and Morbid.** By Charles A. Merckel, M.B., M.R.C.P., F.R.C.S., Lecturer on Insanity at the Westminster Hospital Medical School. Cloth. Pp. 518. Price, \$5.00. London: The Macmillan Co. 1901.

**SIXTEENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH AND VITAL STATISTICS of the Commonwealth of Pennsylvania.** Vols. I and II. Paper. Pp. 1114. State Printer of Pennsylvania: Wm. Stanley Ray. 1901.

**HUMAN EMBRYOLOGY AND MORPHOLOGY.** By Arthur Keith, M.D. (Aberd.), F.R.C.S. (Eng.), Lecturer on Anatomy, London Hospital Medical College. Illustrated. Pp. 324. Price, \$4.50. London: Edward Arnold. 1902. New York: Longmans, Green & Co., Agts.

## New Patents.

Patents of Interest to Physicians, etc., March 4 and 11:  
 694,599. Hernial truss. Robert Arnold, Cleveland, Ohio.  
 694,630. Nebulizer. Herman Golttermann, New York City.  
 694,541. Vaginal syringe. Arthur R. Gordon, Toledo, Ohio.  
 694,751. Hernial truss. Datus E. Huffman, Minneapolis, Minn.  
 694,762. Protector-pad for corns. Samuel A. Level, Hot Springs, Ark.  
 694,666. Pump for atomizers. John Robertson, Cincinnati, Ohio.  
 694,813. Hypodermic syringe. Benjamin T. Winchester, Baltimore, Md.  
 695,270. Vaccine shield. George M. Berlinger, Camden, N. J.  
 694,945. Manufacture of iodine preparations. Max Cohn, Berlin, Germany.  
 695,377. Hernial Truss. Joseph A. Corbett, Medford, Okla.  
 695,198. Insoluble casein and producing same. Henry V. Dunham, New York City.  
 694,971. Rectal instrument. Samuel L. Kistler, Los Angeles, Cal.  
 695,167. Combination liquid measure and sterilizer. J. C. F. McGuff, San Jose, Cal.  
 695,356. Medicine applicator. Burton A. Washburn, Wickliffe, Ky.  
 695,254. Pancreas preparation and producing same. Wilhelm Weber, Stolberg II, Germany.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., March 5 to 12, 1902, inclusive:

Frank C. Baker, lieutenant and asst.-surgeon, U. S. A., from duty in the Division of the Philippines, to take effect June 1, 1902, and

to report on arrival at San Francisco, Cal., to the Adjutant-General, U. S. A., Washington, D. C., for instructions.

Howard W. Beal, Lieutenant and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

Jerome S. Chaffee, Lieutenant and asst.-surgeon, U. S. A., former orders amended so as to direct him to report for duty at the Army and Navy General Hospital, Hot Springs, Ark., relieving Contract Surgeon William E. Musgrave.

August von Clossman, contract surgeon, from duty as attending surgeon and examiner of recruits at St. Louis, Mo., to duty at Jefferson Barracks, Mo.

Louis W. Crampton, major and surgeon, U. S. A., leave of absence from A. G. O. extended six days.

Joseph J. Curry, captain and asst.-surgeon, Vols., now at Fort Bayard, N. M., is by reason of physical disability honorably discharged from the service of the United States, to take effect March 14, 1902.

Carl R. Darnall, captain and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

Edwin F. Gardner, major and surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

Harry M. Hallowell, captain and asst.-surgeon, U. S. A., member of an Army retiring board at Manila, P. I., relieving Major Walter D. McCaw, surgeon, U. S. A.

Louis T. Hess, Lieutenant and asst.-surgeon, U. S. A., previous orders of Feb. 19, 1902, revoked.

Alva R. Hull, contract surgeon, from Jefferson Barracks, Mo., to duty at Fort Logan, Colo.

Charles Lynch, major and surgeon, Vols. (captain and asst.-surgeon, U. S. A.), member of an Army retiring board at Manila, P. I., relieving Major R. W. Johnson, surgeon, U. S. A.

Wharton B. McLaughlin, captain and asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States.

William E. Musgrave, contract surgeon, on being relieved by Lieutenant Chaffee, asst.-surgeon, U. S. A., is granted leave of absence for one month, on the expiration of which he will proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Thomas L. Rhoads, Lieutenant and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

Edward P. Rockhill, Lieutenant and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

Edward A. Romig, captain and asst.-surgeon, Vols., now at Big Rapids, Mich., to proceed to San Francisco, Cal., en route to the Division of the Philippines for assignment.

George A. Skinner, captain and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

John H. Stone, captain and asst.-surgeon, U. S. A., on his arrival in the United States to report for duty at Washington Barracks, D. C.

Henry S. Thrill, major and surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

William E. Vose, Lieutenant and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., as Lieutenant Baker.

Egerton C. Wilson, contract surgeon, now at Owosso, Mich., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ended March 15: Surgeon L. W. Sprattling, detached from the Naval Recruiting Station, Buffalo, N. Y., and ordered to the Naval Hospital, Portsmouth, N. H.

Surgeon O. D. Norton, ordered to the *Richmond* as relief of Surgeon E. H. Marsteller.

Surgeon E. H. Marsteller, detached from the *Richmond* and ordered to the *Lancaster*.

Surgeon E. S. Bogert, Jr., detached from the *Lancaster*, and ordered to Buffalo, N. Y., for duty at the Naval and Marine Recruiting Reid yards.

P. A. Surgeon J. C. Pryor, detached from the Naval Hospital, Newport, R. I., and to hold himself in readiness for duty on the *Massachusetts*.

P. A. Surgeon B. R. Ward, detached from the *Constellation*, and ordered to the Navy Yard, Boston, Mass.

Asst.-Surgeon A. M. Fauntleroy, detached from the Naval Hospital, Portsmouth, N. H., and ordered to the *Illinois*.

Asst.-Surgeon P. E. McDonnold, detached from the Naval Academy, and ordered to the *Olympia*.

Asst.-Surgeon C. M. Oman, detached from the Naval Hospital, New York, and ordered to the *Constellation*.

Asst.-Surgeon W. E. Griffin, ordered to the Naval Hospital, Newport, R. I.

Asst.-Surgeon H. A. Dunn, detached from the *Frolic*, and ordered to duty with the Marine Brigade.

Asst.-Surgeon J. M. Brister, detached from duty with the Marine Brigade and ordered to the *Frolic*.

Asst.-Surgeon U. R. Webb, detached from the *Kentucky* and ordered to the *Iris*.

P. A. Surgeon E. V. Armstrong, detached from the *Olympia*, and ordered to Washington, D. C., and home to wait orders.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended March 13, 1902:

P. A. Surgeon J. B. Stoner, to proceed to Cape Charles Quarantine and assume temporary charge of the station during the absence on leave of Asst.-Surgeon C. W. Wille.

Asst.-Surgeon W. C. Hobdy, to proceed to Savannah Quarantine and assume temporary charge of the station during the absence on leave of A. A. Surgeon W. J. Linley.

Asst.-Surgeon W. C. Billings, to proceed to Ludington, Mich., for special temporary duty. Relieved from duty at Chicago, and directed to proceed to New York, and report to Surgeon G. W. Stoner for duty.

Asst.-Surgeon Dunlop Moore, relieved from duty at Honolulu, and directed to proceed to Yokohama, Japan, for duty in the office of the U. S. Consul-General.

Asst.-Surgeon C. W. Wille, granted leave of absence for ten days from March 21.

Asst.-Surgeon J. S. Boggess, to proceed to Delaware Breakwater, Del., and assume temporary charge of the station during the absence of Asst.-Surgeon C. H. Lavinder.

A. A. Surgeon H. S. Camhiro, granted leave of absence for thirty days from March 5.

A. A. Surgeon J. S. Hough, relieved from duty at Yokohama, Japan, and directed to proceed to Hongkong, China, and report to Asst.-Surgeon J. W. Kerr for duty in the office of the U. S. Consul-General.

A. A. Surgeon W. J. Linley, granted leave of absence for nine days from March 15.

Junior Pharmacist J. E. Beck, upon being relieved by Junior Pharmacist G. A. Morris, to proceed to Mobile, Ala., and report to Medical Officer in Command for duty and assignment to quarters.

Junior Pharmacist G. A. Morris, relieved from duty at Havana, Cuba, and directed to proceed to Fort Stanton, N. M., and report to medical officer in command for duty and assignment to quarters, relieving Junior Pharmacist J. E. Beck.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended March 15, 1902:

#### SMALLPOX—UNITED STATES.

California: Sacramento, Feb. 22-March 1, 1 case; San Francisco, Feb. 23-March 2, 4 cases.

Colorado: Denver, Feb. 24-March 3, 4 cases.

District of Columbia: Washington, March 1-8, 3 cases.

Illinois: March 1-8, Belleville, 4 cases; Chicago, 19 cases.

Indiana: Crawfordsville, March 1-8, 17 cases; Evansville, 8 cases; Indianapolis, Feb. 22-March 8, 31 cases; Terre Haute, March 1-8, 1 case.

Iowa: Ottumwa, Feb. 1-March 1, 42 cases.

Kentucky: Covington, March 2-9, 9 cases; Lexington, March 1-8, 4 cases.

Maine: Portland, March 1-8, 9 cases, 1 death.

Massachusetts: March 1-8, Boston, 17 cases, 6 deaths; Cambridge, 4 cases, 1 death; Chicopee, 1 case; Lawrence, 3 cases, 1 death; Malden, 1 case; New Bedford, 1 case; Quincy, 1 death.

Michigan: March 1-8, Detroit, 3 cases; Ludington, 2 cases.

Minnesota: Minneapolis, Feb. 22-March 1, 16 cases; Winona, March 1-8, 4 cases.

Montana: Butte, Feb. 23-March 1, 2 cases, 1 death.

Nebraska: Omaha, March 1-8, 52 cases, 1 death.

New Jersey: Camden, March 1-8, 1 case; Harrison, March 2-9, 1 case; Hoboken, March 2-9, 2 cases; Jersey City, March 2-9, 46 cases, 1 death; Kearney, March 2-9, 3 cases; Newark, March 1-8, 22 cases, 3 deaths; Union, March 2-9, 1 case; West Hoboken, March 2-9, 3 cases.

New York: March 1-8, Binghamton, 1 death; New York, 60 cases, 10 deaths.

Ohio: Chillicothe, Feb. 22-March 1, 1 case; Cincinnati, Feb. 28-March 7, 15 cases.

Pennsylvania: Philadelphia, March 1-8, 47 cases, 11 deaths.

Rhode Island: Providence, March 1-8, 3 cases.

South Carolina: Charleston, March 1-8, 2 cases.

South Dakota: Sioux Falls, Feb. 22-March 8, 15 cases.

Tennessee: Memphis, March 1-8, 4 cases.

Texas: Houston, March 1-8, 12 cases.

Utah: Salt Lake City, Feb. 22-March 8, 6 cases.

Washington: Tacoma, Feb. 23-March 2, 5 cases.

Wisconsin: Green Bay, March 2-9, 11 cases.

#### SMALLPOX—FOREIGN.

Belgium: Antwerp, Feb. 8-15, 4 cases, 3 deaths; Ghent, Feb. 1-22, 6 deaths.

Brazil: Rio de Janeiro, Jan. 18-Feb. 9, 33 deaths.

Canada: Halifax, Feb. 22-March 8, 3 cases; Quebec, Feb. 8-March 8, 121 cases, 2 deaths; Winnipeg, Feb. 15-March 1, 7 cases.

Colombia: Cartagena, Feb. 17-23, 1 death.

Cuba: Guantanamo, Feb. 27, 1 case.

England: Birmingham, Feb. 15-22, 1 case; Liverpool, Feb. 15-22, 14 cases; London, Feb. 8-15, 64 deaths; Manchester, Feb. 15-22, 1 case; Southampton, Feb. 15-22, 1 case.

France: Marseilles, Jan. 1-31, 1 death; Paris, Feb. 15-22, 3 deaths.

Gibraltar: Feb. 9-16, 1 case.

India: Bombay, Feb. 4-11, 11 deaths; Madras, Feb. 1-7, 2 deaths.

Italy: Basiglio, Feb. 17, 176 cases; Naples, Feb. 8-22, 20 cases; Palermo, Feb. 1-22, 35 cases, 6 deaths.

Malta, Feb. 8-15, 1 case.

Mexico: Mexico, Feb. 23-March 2, 2 cases, 1 death.

Scotland: Glasgow, Feb. 15-28, 8 deaths.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, Jan. 19-Feb. 9, 24 deaths.

Mexico: Vera Cruz, Feb. 22-March 1, 1 case.

#### CHOLERA.

China: Canton, March 6, increasing; 2 deaths among Europeans.

India: Bombay, Feb. 4-11, 4 deaths; Calcutta, Feb. 1-8, 50 deaths; Madras, Feb. 1-7, 4 deaths.

Straits Settlements: Singapore, Jan. 11-18, 5 deaths.

#### PLAGUE—INSULAR.

Hawaii: Honolulu, Feb. 26-March 2, 3 deaths.

#### PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Jan. 18, 11 deaths.

China: Shui Tung, Jan. 23, 100 deaths.

India: Bombay, Feb. 4-11, 531 deaths; Calcutta, Feb. 1-8, 124 deaths.

### SOME POINTS IN THE MANAGEMENT OF THE NEURASTHENIC.\*

JAMES H. McBRIDE, M.D.

FORMERLY PROFESSOR OF NEUROLOGY, CHICAGO POLICLINIC,  
LOS ANGELES, CAL.

The term neurasthenia has not the wide application it had ten years ago. A more accurate clinical observation has narrowed its meaning, and in many cases that would formerly have been called neurasthenia, and which would have been treated as such, are now recognized as nervous features due to some bodily derangement not primarily nervous. Chronic disorder of internal organs may, and often does, predispose to neurasthenia and by interference with nutrition, by exhaustion, or by toxic states, the resistive capacity of the nervous system is lowered so that it more easily succumbs to the ordinary stress of life.

There is, of course, stress in every life; every man, whether he drives a dray or runs a bank, is subject to stress of mind and body, and that which befalls the man of low capacity and rude life may be relatively to his strength and his outlook on the world as serious to him as that other and higher form of stress that daily tests the endurance and the mental integrity of the man of affairs. We find, therefore, that the business or professional man, the day laborer, the young woman stenographer or teacher, or those more unfortunate people who are rich and idle, may all be subjects of this disorder.

A larger proportion of cases of nerve failure have been charged to overwork than facts would seem to justify. Overwork strictly is probably a rare cause of nervous breakdown in men or women. In the healthy body tire comes to the rescue and the wear and tear of work is restored by rest. Nature has so arranged it that if we sleep and exercise sufficiently and eat wisely there is little danger of harm from any amount of work that we may do. The great majority of the people who break down from so-called overwork do not observe these simple rules of right living. Then there are the countless artificial conditions of life, with its multiplying complexities and its grinding cares, especially the unhygienic dress of woman, the lack of proper development in early life by which the physical perfection of thousands of young people is never achieved, so that they begin the adult stage of life dwarfed in their mental and physical capacity and poorly equipped for the struggle of existence; these have more to do with human pathology than work.

Much of the hard work of the strictly mental sort is necessarily associated with heavy responsibilities and attended with care, suspense, anxiety and the worries that, more than the severest toil, cut deep into life or strain endurance to the breaking point. Many neurasthenics were, in health, of the anxious-minded, intense, hurrying, worrying sort of people, and this indicates mental habits that are unfavorable to calmness and frictionless work.

In those who are born with delicate and unstable nervous systems the ordinary occupations of life are liable to develop these habits of worry and anxiety—artificial states of mental strain that are ultimately injurious, or even ruinous to health. One is tempted to lose faith in the conserving tendencies of nature when he sees people with unstable nervous systems and little endurance falling into the high-tension, anxious habits that exhaust the nervous energy and which tend to produce just those disorders that quieter and calmer methods would avoid, and which in the end would enable them to achieve vastly more. Their very tendencies are to self-destruction of a certain kind, and without the protection of a highly organized society and the skill of science they would be eliminated.

The possession of certain mental qualities in a high degree may render one more liable to brain exhaustion. I have known people who, though mentally and physically vigorous, became the subjects of brain exhaustion from the fact of their having an unusual ability for close mental application so profound and intense that they would go beyond their limits without knowing it. Some years ago I heard a gentleman, who was then and is now a professor in a university, deliver a lecture of an hour and a quarter. He spoke without notes and the talk was so systematic in arrangement, so compact of matter, so condensed and clear of statement, and showed such unusual powers of mental concentration that I afterwards remarked to him that his ability to apply his mind and hold his facts in consciousness was dangerous, as it involved a strain that one might easily be unconscious of and that might result in brain tire. Two years from that date he developed insomnia and inability to apply his mind and for eighteen months was unable to do any mental labor. These cases of pure brain tire are not so common as the more ordinary forms of neurasthenia, but the condition may develop in any one who has serious interests and great power of mental concentration. Every man has what may be called his breaking strain, and the wise man knows his limits and keeps well within them.

Many neurasthenics have one primary cause for their disorder that in a measure modifies the effects of even their environment, a cause that lies deeper than any individual life experience. That cause is found in an

\* Read before the Wisconsin State Medical Society at Waukesha, Wisconsin, June 28, 1901.

inborn instability of nerve element, some organic defect in its essential structure which makes many men and women unequal to the strain of adverse conditions, sending one to the bed of a nervous invalid, another to the hospital for paralyzed and epileptic, another to the mad-house.

The neurasthenia that results from shock or traumatism, such as occurs in car or other accidents, is often associated with hysteria. It is not always easy to decide how much there is of actual injury in these cases, and how much of simulation. A pending suit for damages and frequent examination by physicians do not furnish them with the conditions that are the first requisite to recovery. Many of them need to be separated from friends and relatives and have some form of rest cure. Unquestionably injustice is sometimes done people who, though not having received an injury that has produced a gross lesion of the nervous system, have had as a result of the terrifying fright and violent shock from a railroad accident an injury to the nerve centers, which, though we may not be able to localize it, may at the same time be serious.

It is now a commonplace that many cases of neurasthenia are due primarily to derangements of the alimentary tract. Very much of the good of the milk diet in the rest cure is probably due to the fact that the stomach, which is in many of these cases primarily or chiefly at fault, is given a new and restful regimen, and that by this means a chronic functional incapacity is relieved.

Neurasthenia from over-excitement and dissipation occurs most commonly in those who, having wealth and leisure, waste their strength in frivolous interests or in irregular living; and of these the frivolous interests are probably the more frequently harmful. In the hygiene of life there is nothing that contributes more to health and happiness than serious interests—interests that are based upon pleasure in work and a healthy desire to be every day doing something worth while.

Not long ago I saw a lady of 40 who has a form of neurasthenia that is rather common among the well-to-do. Her father was a man of large means, though a periodic inebriate, who had never required work or responsibility of his children. His only son was once treated for brain exhaustion and is a man without occupation, who travels about the world for pleasure, though, as he says, for health. The sister to whom I refer had, as a girl, superior ability, a taste for serious reading and an indifference to society and gaiety. She was always indolent, ate heartily, exercised little, and did no work, and grew up thoroughly selfish and self-centered. At 30 she had trouble sleeping and some indefinite neurasthenic symptoms. These have increased until now she has insomnia, numerous morbid sensations in different parts of her body, a feeling of fullness of the head, frequent depression, a fear of open places, a dread of seeing people, and a fear of fainting if she chances to meet people on the street when alone. Her appetite and digestion seem perfect and her nutrition excellent. Much of her time is spent on the bed, with an occasional walk or ride, and either of these occasions as much discussion and preparation as a well person would devote to getting ready for a week's journey.

In this case there was probably a predisposition to nervous disorder; a purposeless life has done the rest. This woman is not a malingerer; she is a victim of idleness, high living and of weakened volition, and she will be fortunate, indeed, if she escapes insanity. To cure such a person involves the remaking of a character, and this, too, upon the foundation of a bad inheritance.

Many neurasthenics are hysteric in some degree, and this class needs strict seclusion and control. One recent writer speaks of neurasthenia as being synonymous with hysteria. This, it seems to me, is a wrong view to take. Because a case shows certain symptoms that are characteristic of hysteria, or that usually are associated with it, we are hardly justified in classing it as hysteria.

The cases of neurasthenia that have a pronounced hysteric element are, of course, much given to pretense and exaggeration. That a person is partially or chronically hysteric does not, however, justify us in considering the case a light one. We can no longer regard hysteria as in any sense a trivial disorder. In all its phases it is serious, for its more thorough study of late years has shown that it is, perhaps, largely and primarily an affection of the higher cerebral centers, those last evolved and unstable layers of nerve cells that in health are concerned in the higher brain functions. It has, therefore, a very definite pathologic basis; in it there is a dissolution of these higher brain centers to that degree that, though actual insanity may not exist, a lowering of the psychic functions takes place; there is an inferior order of consciousness, thought is less orderly, emotions less controlled, the moral sense perverted.

In all cases of neurasthenia there is the mental element which is always an important part of the disease, in some cases the most important part. It is shown in inability to fix the attention, the feeling of mental tire, the loss of interest, the weakening of volition, the impairment of memory, and other phenomena that are only too familiar. The general functional disorder of the nervous system which, with its endless train of symptoms, is always present and uppermost in the patient's consciousness, fixes the mind upon the body and tends to limit the patient's thoughts to a certain set of morbid sensations. The normal interests are dropped one by one; more and more the thoughts revolve about the sensations of the body until finally the attention is centered there. This hyper-consciousness of bodily ailments may become a true hypochondria, and many neurasthenics pass into this more pronounced morbid condition, while others become insane. These are among the cases of neurasthenia that to be cured need the moral discipline, the restful change and the limited and simple environment of seclusion.

Not all neurasthenics need to be completely secluded. Some may be treated in their own homes, having, if necessary, partial separation from the family. Others can be cured without any separation, though such cases are rare.

For those who have partial rest prescribed it is sufficient that they rise late in the morning, say not earlier than 9 o'clock, and that they lie down for two hours about the middle of the day and maintain absolute quiet. Late rising in the morning is advisable for all neurasthenics. Through imperfect nutrition, I suppose, and from absence of food during the night hours, neurasthenics feel badly on waking; they have that "morning tire" and "miserable feeling" that are so familiar to those who have seen much of them. They are better after taking breakfast, better still after noon, and unless there is some special cause for tire they are still better in the evening. Those patients who can be up for a short time, both in the forenoon and afternoon, are easily kept busy, for their meals and rests and walks, and the readings by the nurse fill in the time, so that they have little opportunity to think of self and review the ever-moving procession of their symptoms.

A certain proportion of neurasthenics need to be removed from home and have absolute seclusion and perfect rest. The moral effect of this is beneficial, and the quiet and rest and intelligently managed monotony give just the opportunity needed for repair of the exhausted nervous system. The details of rest and seclusion are too familiar to need restatement. The persons for whom it is adopted need to be carefully selected. I have seen it applied for two and three months to the lasting harm of patients who did not need it for a day.

As a rule, complete rest should be prescribed for those who show great debility, those especially who are emaciated and anemic; whereas those in whom nutrition is good will often do better on partial rest. There are certain cases of neurasthenia that are anemic and weak and yet corpulent and florid. Their outward show of vigor is deceptive and they sometimes need complete rest and seclusion. In other cases of this sort partial rest is sufficient.

Thirteen years ago I had as a patient a woman whose life had been a very trying one, and who was given to overeating and took little exercise. When I first saw her she had been confined to her bed for a year, with so-called neurasthenia, and to the house for a much longer period. She was short and quite corpulent, weighing 170 when she should have weighed 115 pounds. She was given partial rest and strict diet. When she began to exercise she could only walk about her room. This was gradually increased, and in four months she walked six and eight miles a day, and at the end of six months was in good health and weighed 125 pounds. During all these years she has continued her exercise and has remained in perfect health. In this case complete rest was not required and would have delayed rather than hastened the cure.

Having prescribed rest for a patient, one must be careful to see that it is not too prolonged, for if kept at rest too long the invalid habit may be aggravated rather than benefited. Many patients enjoy the seclusion and rest to such a degree that it may easily become a luxury to them; and though they may be temporarily better from the treatment they come to regard it as a pleasant resource in case of a breakdown and look upon a return to it as a well person might look forward to a trip to Europe. I have seen a number of persons who spoke with apparent pride of the frequency with which they had taken the rest cure, and some of them I am sure would have been far more benefited by walking, riding and golf.

In the management of the nervous invalid the personality of the nurse is of vital importance. The less experienced the physician with this class of cases the more important that an experienced nurse be had. Experience, however, will not alone serve, nor even great skill in ordinary nursing. The nurse, to successfully manage the neurasthenic, must possess those qualities that are only born to one; qualities that can not be talked into one in lectures, nor put into one's character through the poor medium of books. There are many trained nurses of large experience who can not compass the morbid and contradictory character, nor meet with success the caprices of the nervous invalid. No nurse should be put in charge of a neurasthenic who has not that quality of mind that enables her to understand that however much of exaggeration and shamming her patient shows, she is yet really a sick person; and for a nurse to abstract this conclusion from the morbidness and selfishness that lies before her is a thing that many nurses are unequal to. If a nurse has not this under-

standing of her patient, or has not an intelligent yet unindulgent sympathy for her, she falls far short of being the ideal nurse. She will not be as patient, she will not have the same interest, she will not be as quick to see the necessity for diversion nor so prompt to seize upon opportunities to supply it.

Frequent feeding is not applicable to all of these cases, even those that are kept in bed. A strictly milk diet does well with some, but most of them do better with some solid food. It is an important point in giving them food that each meal should be digested and the stomach be empty before the next is given. The stomach works under the law of periodicity, and this can not be ignored and the organ kept constantly busy, however light the work that is given it. Many of these patients can digest some meat and with great benefit to their nutrition, and this though there may be functional indigestion. In the evolution of the function of digestion the ability to digest proteids is first established, then starches, and lastly fats. In failure of digestion—that is, digestion of functional kind—the reverse process takes place, the ability of the stomach to digest fats fails first, then that of starches, and then proteids. The only thing in milk that really requires the full and active work of the digestive process is the proteid, for the sugar element is practically predigested, and the milk fat is already emulsified. By giving milk in functional indigestion we obtain these three classes of food, and yet demand of the stomach the performance of the one function that is least impaired, that of digestion of proteids. There are some neurasthenics in which there is serious functional indigestion, and yet tender meat can be digested with ease and benefit.

Recently I began treating a neurasthenic lady who had been living almost exclusively on liquid diet for six months and who during that time had not eaten any kind of meat. Her stomach was somewhat dilated and from long disuse the muscle fibers were probably greatly atrophied. After two weeks of intragastric faradization I had her eat a beefsteak at noon, and she had less trouble with it than she had previously had with milk.

In the various steps of the rest cure the time when exercise should be begun is a difficult matter to decide, and it is often a trying time both for the physician and the patient. Neurasthenics are generally people who have not been believers in exercise, and for the person who has been long bedridden with this trouble any unusual muscular movements start all the demons of morbid peripheral sensation. The flabby and wasted muscles, the feeble circulation, make voluntary movements irksome; the unused nerve fibers when compelled again to functionate give rise to various uncomfortable sensations that seem big in the patient's feeble and hyperesthetic consciousness and make her feel that it is impossible to go on. The physician must decide how much exercise the patient is to take and when, and there is nothing in the whole line of treatment about which he should give more careful directions. It can not be safely left to the patient, nor should the nurse be allowed to use her judgment. The patient needs to feel that the physician's judgment is what she is conforming to, and that he is taking an immediate and particular interest in what she is doing. Otherwise when she begins to exercise and suffers the intense discomfort that so many do she will give up discouraged and sink back into her old condition. Another important point is that the patient's strength must be carefully gauged and her exercise added to every few days, never allowing her to

take less and at frequent intervals requiring that she take more.

It is proper here to refer to the feeling of tire from which so many patients suffer. In health the sense of bodily existence is the summing up in consciousness of the physiologic activities of different parts of the body. The physical sense of well-being is likewise the expression of the harmony of the organic processes; the life and work of all the myriad cells that compose the organs are echoed in the brain, and make up this one general sense of pleasurable existence. When our organic sensations are altered pathologically in one or many parts we get morbid impressions from those parts, and as a man thinks his body to be in the condition that he feels it to be, the number, persistence and strength of these impressions determine largely the degree of ill health; they may determine whether or not he shall be an invalid.

These abnormal bodily sensations of the neurasthenic, by persistently obtruding themselves in consciousness and causing the attention to be fixed upon them, finally induce a morbid mental element and later, the mind being withdrawn from other interests, owing to the limited and narrowing effects upon it of the ever-present disordered feelings, the patient can not forego the luxury of listening to the morbid reports that come up to the brain from the various organs.

The feeling of tire, which is really pathologic and which many neurasthenics have, adds to their mental suffering. Many patients, after a night's sleep, wake with headache, general discomfort and a feeling of mental and physical disability that makes any exertion seem difficult to them. At other times, or possibly when the patient's condition is really worse, there may be little or no sense of tire, even after exertion. Many neurasthenics have this "anesthesia of the sense of tire" to such a degree that they have no guide as to when they have exercised sufficiently. As the nervous system is irritably weak they get up a certain amount of fictitious excitement in everything they do and rush on until exhausted. It is very important, therefore, that the physician regulate the patient's exercise in kind and amount from day to day. It is important that the patient be not allowed to overdo, for this means a halt in recovery, and though it may be only temporary, it is serious for one whose will-power is weak, whose self-confidence is lost in timidity and with a disposition to consider any trifling failure an important matter.

The rule in regard to exercise is to avoid serious fatigue. We have here two things to deal with that must both be properly estimated, the actual weakness of the nervous system by which its limit of energy is soon reached, and that feeling of disability or want of strength which is the exaggerated expression of the nervous weakness. It is a most difficult thing to estimate the amount of the patient's real strength that can be depended upon from day to day, to know how much of the exhaustion that she feels is genuine, and how much of it, though real to her, is due to pathologic habit and how much of it she simulates.

Here appears the importance and the advantage of understanding the mental condition of the neurasthenic, for in addition to the physical gain the mental state of the patient is an important guide in judging of what the management is accomplishing. Every neurasthenic is morbid in feeling, and this means a lowered mental tone. The nerve centers, weakened from overstrain, poisoned by tissue waste, are hourly assailed by morbid impressions from the periphery until these come to occupy

consciousness; they are also weakened in ability to appreciate normal impressions while they seem to become hyperesthetic to those that are abnormal. The bodily habits and mental life are adjusted to this morbid revelry of weak and disordered nerve centers, and the physician has to change all this by practically recreating normal functions and healthy habits. When from week to week a perceptible gain in ability to exercise has been made and the patient brought to see the gain, and having been established in it, then another addition may be made, and so on, step by step, toward health. The neurasthenic, like the learner everywhere, learns to do things and gets confidence only by doing them, and in this way she regains the lost habits that belong to health.

Outdoor walks should always be taken on the ground, never on pavements or verandas; the solid, unyielding character of a stone pavement is bad, and its evenness of surface is worse, for the same muscles are brought into action at every successive step, and the repetition, like the movement of running a sewing machine, is exhausting. The natural place to walk is on the ground. Man's ancestral habits are here, as elsewhere, strong upon him, and the spring and unevenness of the earth has in it the gift of health for the pedestrian. Walking on a pavement is tiring to a well person, and is quickly so to the invalid; and as the exhaustion from muscular movement is largely in the nerve cells, the nervous invalid should avoid all exercising in this way. Walking on the ground is stimulating to a certain degree; it is not only a good general tonic, but especially so to the heart.

Neurasthenics should not climb hills until they are far on the road to recovery, and even then should go about it cautiously. The heart muscle of the convalescent neurasthenic, like other muscles, is weak and needs to be gradually redeveloped before any strain can be put upon it. The person who, in climbing a hill or riding a bicycle, is out of breath, should understand that he is primarily out of heart; and in the recent invalid it is easy and dangerous to pass the limit of physiologic fatigue of the heart.

All walking, except where the patient is weak and only beginning, should be rapid, though, of course, being adjusted to the strength of the patient. Many patients only saunter, and there is, therefore, lack of interest in the exercise and some loss in the benefit from it. All walking that is done for exercise should be brisk. A brisk walk of a hundred yards is better than a saunter of five hundred yards. It requires that the attention be directed to what one is doing, so that there is not only the forgetfulness of self, but the tonic of healthy effort. Brisk walking stimulates the circulation in a way that careless walking does not; it forces the blood into unused channels and augments function. Such exercise has a therapeutic value which, if it could be concealed in a prescription written in Latin, might be the fortune of one who chose to utilize all its possibilities. Brisk walking does not mean haste. Emerson has been good enough to tell us that all haste is vulgar. It simply means the normal and reasonable speed that belongs to the healthful, interest-taking ways of doing things. The steady-going and speedy gait of the healthy, hopeful, self-confident person implies character, and has back of it the momentum of health and the unconscious energy of vigorous interest. I never knew an indolent person or an indifferent person to habitually walk briskly. The hypochondriac and the melancholiac saunter and shuffle; the cheerful, determined person steps off

as though there was pleasure in the effort and an object beyond it, and it is certainly an education in normal interest for the convalescent to thus healthfully strive for health.

A morning sponge bath is bracing to the nervous invalid, and relieves in a measure the feeling of weariness that they so generally have on waking. The bath should not be cold. The first baths should be only eight or ten degrees below the body temperature; and, later, as the patient grows accustomed to them, the temperature may be lowered to fifteen or twenty degrees below that of the body, provided it never is uncomfortable and never produces chilliness.

I indulge the eccentricity of being a disbeliever in morning cold-tub baths.<sup>†</sup> There are certain vigorous people who, long accustomed to them, may continue the practice with benefit, but I do not advise people to begin it. To most people, at least delicate people, a cold bath is a shock, and for this reason may be depressing to the nervous system. Recently a maiden lady of 60, a particularly vigorous and active person, consulted me for various indefinite nervous symptoms of a functional kind. Investigation showed that for ten years she had been taking a full cold morning bath. She also said that when she felt a little languid in the afternoon, which she frequently did, she took an additional bath. She insisted that the bath stimulated her and braced her for the day. I explained to her that the stimulation was like the toper's morning nip, and that I thought her nervous trouble was due to her baths. She discontinued them with some reluctance and considerable skepticism. In four weeks her nervous symptoms had disappeared, and this without a dose of medicine or any change in her daily habits.

The temperature of a cold bath is relative to the vitality and reacting capacity of the person who takes it. A temperature of 78 will be as uncomfortable to one as a temperature of 60 to another. To specify, therefore, that a cold bath or a cool bath shall be of a certain temperature is not as definite as it seems, for what we need to measure is the vigor and resistive power of the patient, and this is as various as individuals.

There is but one safe procedure with all delicate people, and that is to have them begin with a bath very little below normal, and gradually reduce it from day to day, or rather from week to week. So far as neurasthenic women are concerned I think there are few who should take a sponge bath below 78. What most of them need is a stimulus, not a shock, and this is got with water that is very little below normal. The vigorous rubbing after the bath has a large share, I think, in the general benefit, not only because of the exercise it involves, but also by the stimulation of the circulation the nerve centers are benefited at a time in the day when in delicate persons their vigor always languishes. The stimulating effect of the morning bath is much increased by adding common salt or sea salt to the water.

Many an insanity is due to a neglected neurasthenia; many a neurasthenia is due to a neglect of minor disorders of body that originally were trivial. As there is a natural history of every case of insanity that reaches far back to antecedent conditions in the life history of the individual, so there is a natural history of neurasthenia that in most cases antedates by years the fully developed illness. The nervous breakdown in these

cases is rarely as sudden as it seems; it is rarely as recent as it seems. Outside of those cases in which it is directly and strictly due to recent stress it is usually slow in development, and is due to habits of unwise living that have extended over years or a lifetime.

It is these habits that are to be corrected first by the influence of a healthy environment and the firm and steady pressure of a stronger will, and later by the persistent self-care and self-discipline of the patient.

This being the case there is no class of diseases in which it is so necessary that the physician have a method as in these cases, and this must be based on an instinctive knowledge of human nature and of the special perversions of it that neurasthenics show. It is a significant fact that Weir Mitchell, who first established a rational plan for the treatment of a certain class of neurasthenics, is the author of those beautiful essays called "Characteristics," which show a thorough knowledge of the ways and byways of the mind. It is just this knowledge that is here required, with patience to apply it in practice, and adapt it to the entangled but variable morbidness of the neurasthenic state that never exactly repeats itself in two people.

Because there is a certain amount of reduction of mental power and weakened volition, it is not necessary to consider these people hypochondriacs or hysterics. We see in the neurasthenic in an exaggerated and somewhat chronic form what we see as an after-effect of many acute illnesses. It is not so much the symptoms referable to the nervous system or their special grouping that gives neurasthenia its significance, but it is rather their continuance and persistence. The most serious thing in the history of neurasthenia is the tendency to chronicity, that is, its tendency to involve like a slow infection the individual life habits, so that we find in a given case healthy interests have waned, consciousness has set in certain abnormal ways, and the mental life has been adjusted to certain morbid habits that tend to a monotonous and devitalizing repetition. As nothing rises to consciousness in the neurasthenic mind but is the issue of morbidness, it is inevitable that the patient will be egoistic, self-centered. In the presence of the insistent and dominating diseased self the person is powerless even to attempt. To give these people abundant food and tonics and a luxurious rest and fat them up temporarily is not so difficult. To look at each patient, however, as a problem, not so much of cure as of both cure and character making, is the proper way and the only way, but the more difficult way. One must first thoroughly understand the mentality of his patient, he must supply himself the will power which the patient has temporarily lost, he must meet all moods with patience and every whim with gentle and unoffending firmness, allowing no halts in progress, conceding nothing to the patient's doubts and fears, and yet doing this with such diplomacy as not to excite dislike or antagonism.

In this view the physician's task is not an easy one. He has to pick his way through a labyrinth of morbid mental and physical phenomena, recognize exaggeration and pretense, estimate the value of this symptom and that one, and in the end make an impartial, accurate and just estimate of the case, and ultimately to plan, not for two or three months, but for a lifetime.

In these cases the first thing to be done is to provide a secluded and restful life, and then to introduce, unobtrusively, healthy interests, as increasing strength permits. An essential preliminary to bringing to the patient new interests is to forbid her to speak of her illness. That this is done with those who have the rest

<sup>†</sup> Since this paper was read, I have added the name "tub" in order to make my meaning clear. Hydrotherapy has an important place in the treatment of functional nervous disorders, but it should only be applied under the detailed directions of the physician.

cure hardly needs the saying, and with them its enforcement is easy. Those who have more liberty and who go about, need to have the rule made absolute and rigidly enforced. The patient should be forbidden to speak of her symptoms even to the physician or the nurse, once she has given her history fully. When her symptoms cease to be discussed, and she is not allowed to even refer to her illness, its hold on her consciousness inevitably weakens. As in health we have but half learned things we have not given expression to, and as expression doubles the value of knowledge, so in pathological conditions such as this the frequent repetition of these insistent symptoms fixes them in the mind. To the patient they are important and absorbing, and are overgrown with pampering and repetition, but they can not long survive un pitying neglect or firm repression.

The way for the neurasthenic to keep well when once she is cured is to live a simple but active, and if possible, outdoor life; such a life is restful of cares and curative of worries, a builder of endurance and creative of stamina. Man is an outdoor animal. He toils at desks and talks of ledgers and parlors and art galleries, but the endurance that brought him these was developed by rude ancestors, whose claim to kinship he would scorn and whose vitality he has inherited and squandered. He is what he is by reason of countless ages of direct and unprotected contact with nature, in comparison to which his erect spine, his civilization, his learning, his palaces, his neurasthenia and his hysteria are but affairs of yesterday. Man, therefore, is of nature and belongs to nature; and when he lives outdoors and works with his hands, and in quiet and unconscious ways joins in the silent and unhurrying life that goes on about him, he is in a measure returning to the life in which his body was fashioned and which furnishes the simplest and best nourishment that his body can have. These conditions, if rightly used, would prevent much of the invalidism that there is in the world; they would also cure much invalidism that has its origin in the monotony of care and worry, or in the exhaustion of hard and wearing toil, and that kind, too, that grows rank in the tapestried and cushioned parlors of the luxurious and idle.

It is under some such normal conditions as these I have indicated that the recovered neurasthenic is to live if the recovery is to be made not only complete but permanent. It is one thing, and relatively an easy thing, as I have said, to provide for a neurasthenic, rest, seclusion and frequent feeding, and in a few weeks have the patient fat, comfortable and in apparent health. My experience has been, however, that when the neurasthenic has been brought to this stage of recovery, she has but started on the road to health, and it is because the last half of the cure is not finished that so many of them relapse.

The crop of neurasthenics will never be reduced unless we use our authority and our influence as physicians to get those who recover to live as they ought; to get them to live simple, healthy and active outdoor lives; have them if possible cultivate a taste for nature and an interest in and fondness for plain and natural living, for this is a constant support to the nervous system, weak or strong, and the best defense against the bad effects of work indoors. I long ago decided that the treatment by which the neurasthenic woman could have her exhausted nervous system temporarily rested and braced up so that she would appear and feel normal was but a small part and the least important part of the cure. When this stage is reached and the patient, always a

poor judge of her condition, begins to consider going home, the physician's duty of instructing her how to live begins. She is to distinctly understand that the attack through which she has passed may have permanently lowered the resistive capacity of her nervous system, and that if the old habits and conditions obtain the disease will surely return. By persuading women to live properly I have prevented many relapses; and I have the satisfaction of knowing that many of my patients have for years enjoyed better health by living up to a few simple rules than they ever enjoyed before.

Three and a half years ago I took charge of a neurasthenic young woman 23 years old. She had an older sister who was insane; her father died of Bright's disease and hemiplegia, and her mother of some obscure brain disease. She had been a moody emotional child, and was self-conscious, self-centered, jealous, anxious-minded, and with an inveterate habit of worrying; she was sleepless, subject to headache, of poor digestion, with morning tire, inability to exercise, more or less mental depression; she was timid, apprehensive and irritable, with occasionally a day of cheerfulness and a feeling of comfort and well-being. If this young woman had been put to bed for a few weeks she would have soon been apparently well; I could have sent her home as one of the miracles of the rest cure, and under the disguise of a certain amount of artificial fat and manufactured plumpness, and a deceptive and superficial vigor she would have advertised me to her friends and later would have returned to have the miracle repeated. She had been brought up in a parlor and in all her life had never known any object but self, nor any interests but these that were personal and trivial. She had been surrounded by numerous relatives who were by turns harshly critical and unwisely sympathetic; in consequence of these conditions she had early developed an unhealthy emotional nature while petty and vexatious interference by others had worn to shreds her delicate and unstable nervous system.

Her chief need seemed to be that of a normal life, healthy interests, healthy habits, and to be educated in self-control. For six months she lived quietly with a nurse, never seeing relatives and others only occasionally. She rested two or three hours a day; she had massage, light gymnastics and proper diet. Her exercise was gradually added to and persistent attempts were made to interest her in some outdoor sport or some branch of natural history that would make outdoor life attractive. After trying botany and geology and insects, I finally got her interested in birds, and at the end of eighteen months she was an expert in bird life, an amateur photographer, walking miles each day and climbing mountains, and without one physical ailment; she became normal in mind and body, and possessed of a vigor that few women can boast of. At the end of three and a half years she is still living an outdoor life, without any prospect that she will ever again become an object of pity to her friends, nor of pathologic interest to her physician.

This case is related not because the result is unusual but to show what can be accomplished with a person, who, from childhood, had never seen one normal day and who had also the misfortune of a bad inheritance. Yet out of this mass of mental and physical morbidness I developed a healthy person and created a normal character; I epitomized in eighteen months the discipline and experience that she should have had in childhood

and girlhood, and this was all done by the simple method of creating healthy interests that led to normal habits.

Every physician knows how large the number of people is who ought to be well and strong, who yet amble through an inefficient life of semi-invalidism, or who become pronounced neurasthenics, simply because they have never learned what they ought to do, and might easily do in order to maintain vigorous health. Very many of these people, most of them I think, can be essentially made over by the physician; even those who have reached middle life may adopt new habits of mind and body and enjoy a vigor of health that even in their younger days they had not known. I know from personal experience that it is quite possible for the physician to practically recreate a character and thus change the entire subsequent life history of an individual. This requires that the physician be something more than a mere purveyor of drugs; that he should have the larger view of his calling. His patients are thus not merely visitors at his office in whom he has a transient interest; they appear to him in their relation to society in the larger sense, each one a problem in right living. In a certain sense, therefore, he is responsible for their future; for not only is he, in this special class of cases at least, a mender of minds and bodies that have been broken in the stress of life, but if he sees clearly the social significance of his mission and values it properly he becomes what every physician ought to be, a maker of character.

#### MEDICAL EDUCATION AND THE STATE.

WALTER A. WELLS, M.D.  
WASHINGTON, D. C.

As one of the significant indications of our country's intellectual growth might be cited the very general active interest which is being taken in the advancement of technical and professional education. Although not with equal pace with other branches of learning, great progress has been made likewise in the methods of teaching medicine. Twenty-five years ago the best medical colleges of which we could boast were satisfied to have the student attend but two courses of lectures, each of these less than four months' duration, with none or but very slight provision either for clinical or laboratory studies. The lectures were almost wholly didactic and confined to a few practical branches; the "fundamentals," as they are called, and the allied scientific branches were either neglected or at least but very superficially treated. Today all first-class medical colleges have a four-year course of study. Each student is obliged to devote a specified number of hours to laboratory work in bacteriology, pathology, chemistry, pharmacology, and perhaps biology. Most important of all, he is brought during his senior years face to face with diseases in order that he may learn from actual observation how to diagnose and treat them.

#### VARIETY OF COLLEGES.

But these advances in medical education demanded in no small degree by the rapid evolutions of medical science, unfortunately do not apply to all schools alike. Many of them remain far in the rear of this standard, and some in their general methods of teaching are hardly in advance over those of twenty-five years ago. There still flourish—thanks to an indifference in public opinion which in a matter so deeply affecting the welfare may be called criminal—in different sections of the country a number of fake institutions, the so-called diploma mills, where education is nothing more than

an empty pretense. All of these colleges, the worst as well as the best, are alike legalized by the state and granted the privilege of conferring the degree of M.D. In some states, in order to be permitted to practice medicine, it is only necessary to present the diploma of a "legally chartered medical school." As under this head come the diploma mills referred to, the frauds, or it may be the fools, the only classes of material which these mills turn out, are free to prey upon the public; and who can say what will be the consequences to the health and happiness of those who may come within the sphere of either the nefarious activity of the one, or the blundering practices of the other? Although people seldom inquire into the educational training through which their medical advisers have been, there are the best of reasons why they should do so, bearing in mind on the one hand how great are the possible differences of degree and thoroughness, and on the other the fallibility of human judgment as to the fitness of a physician to practice his profession. Only those who are themselves technically trained can rightly judge the degree of technical training in others. Many physicians have, because of their pleasing manner and address, their fine clothes and their stylish equipages, so imposed upon the public as to cause themselves to be regarded wonderfully wise physicians. It is manifestly unfair to those who have labored hard and conscientiously to earn their degrees from the higher-class schools, and it is likewise unsafe for the public who are incapable of discriminating, that such unequal preparation and fitness to practice a profession, should be similarly rated and recognized. As we shall see later on, many states in their laws regulating the practice of medicine have seen the injustice of the thing and have endeavored to rectify it, but influences brought to bear of a financial kind, joined to the ignorance and prejudices so generally prevailing in these matters, have conspired to prevent or at least retard progress. It is only through the medical profession that advance is made and every triumph achieved in the direction of a higher standard and more uniform grading of medical education, and to its honor be it said that none but the loftiest motives have actuated it in the pursuit of these ideals. If those who have consecrated their energies to this purpose can be said to have had any selfish motives at all, it is no less honorable one than to elevate the standing and dignity of the profession to which they belong, and to avoid as much as possible the opprobrium unjustly visited upon all because of the unworthiness of some. But if we admit this to be a selfish motive, there is another undeniably altruistic which I am sure is no less often the inspiration of the efforts to secure higher standard of education, viz., the wish to protect the community from the incalculable evils that ignorant and incompetent practitioners may inflict. Two ways have been pursued by those interested in accomplishing these ends: 1. the elevation of the standard of education; 2. the erection of legal barriers in the form of state laws which will prevent any but capable physicians from engaging in actual practice. For the promotion of the first-mentioned object associations of colleges have been organized, representing the various schools, homeopathic and eclectic, as well as the regular. The Association of American Medical Colleges, for example, which with its southern branch includes nearly all the regular schools, have now made it a condition of membership that there must be a four-year course of medical instruction, each course being of at least six months' duration, and no two of them be given during the same cal-

endar year. Nevertheless, as may be readily understood, the colleges in the association as well as without, may vary greatly in their curricula, methods of instruction, excellence of laboratory appointments, clinical facilities, etc.

In a report that was made of the condition of medical education in the United States at a meeting of the association referred to, June 5, 1899, at Columbus, Ohio, it was disclosed that most widely ranging disparities existed among the different medical colleges as to the total number of hours of college work and the number of hours required of each student of attendance upon clinic and in the number of clinical cases available. As to the number of hours of total work, while there were but twenty-six colleges which demanded over 4000 hours, there were seven which required between 3500 and 4000, and seven others between 3000 and 3500; eleven between 2500 and 3000; two were satisfied with from 2000 to 2500; and three did not require even 2000 hours of total attendance. As to the number of hours of clinical work, it was stated as the opinion of the committee, that 750 was the minimum which ought to be demanded. Four colleges were reported to give 1200 hours, but there were six others which offered less than 300 hours during the whole four years. The same inequality was found to obtain in the different colleges in the number of patients which they could command for the benefit of their students. While three of them had from 40,000 to 100,000 a year, there was another three which gave no evidence of being able to furnish a single case for the purposes of study.

#### AMERICAN AND EUROPEAN COLLEGES.

We have in this country, without doubt, a few medical schools which graduate men as scientifically trained and as fully equipped to practice medicine as any that are to be found in the world. But at the same time others exist, the worst that are to be found in the world. In European countries where the medical institutions are under governmental control, and are uniform in their requirements and curricula, the conditions which exist with us are unintelligible. They follow the rule of judging us from our most inferior output. Americans studying abroad have too frequent opportunity to observe with what contempt foreigners regard the medical institutions of our country.

It is no wonder, when their opinions have been formed from either their acquaintance with recent graduates of the diploma mills—always pretentious notwithstanding their ignorance of the rudimentary principles of anatomy—or with the practitioners who have succeeded in becoming rich from their practice, despite their incompetency and have gone abroad to make a vulgar display of their ignorance as well as their money.

Even some of the popular plays and novels, as remarked some years ago by Dr. Andrew D. White, Minister to Germany, have adopted this subject as a theme and have amused the German public by their representation of the American doctor parading a diploma which he has bought with his dollars.

Indeed, if we compare the institutions of our country with those of European countries merely with respect to the length of time the student is required to devote himself to the study of medicine, we find that even our best schools are somewhat behind. We have seen that the Association of American Medical Colleges requires a four-year course as a condition of membership. But in Germany the course of study covers a period of nine years, though in exceptional instances a

student may get through in seven. In Switzerland it is six years, in Great Britain the minimum is five years; in Sweden, where the profession is held in particularly high esteem, the student must spend ten years with the faculty of medicine before getting his degree. In Austria, France and Italy the course is generally six or seven years.

While such is our estimate of the superior mental caliber of the American that we believe he can accomplish in four years as much as many foreigners can do in five or six, it is nevertheless true of the study of medicine in particular, that the length of time necessary to master it can not be much shortened even for the most brilliant geniuses. This is owing to the circumstance, in the first place, that it is almost wholly an empirical science, which, consisting of facts, observation and dogmatic statements, can not be known by intuition, but is only to be acquired by study and experience; in the second place, it is a progressive science, continually changing, growing and specializing, therefore demanding of its devotees much extra study to keep abreast with the new theories and new methods, which are constantly being proposed and inventions and discoveries constantly being made. But our schools, it is well known by those who have studied abroad, compare unfavorably with the foreign not only in the length of, but in the character of the course of studies. Owing to the advantage of having government support, their laboratories are magnificently appointed and furnished with scientific appliances, material, instruments of precision, etc., indispensable for teaching branches such as chemistry, physiology and histology. To cite an example, the Prussian government contributes yearly to the Berlin University of Medicine fifty thousand dollars exclusive of salaries.

The facilities for clinical instruction in the European countries are likewise greatly enhanced by reason of the fact that the state controls the hospitals as well as the universities, and makes one subserve the ends of the other. Thirdly, the professors and corps of instructors are not self-constituted, as in this country, but are selected by reason of their scientific attainments alone, and advanced step by step from a lower to a higher position in the faculty, whereby they become by experience better trained in the art of teaching their specialties, that is to say, they become not only expert physicians but trained teachers. Now, what is the truth with regard to the medical colleges of the United States? The chief and foremost cause of all other evils is the fact that they are mere private enterprises, organized and conducted in the interest of the stockholders and not of the students. A half-dozen or so of men, unpossessed of even the semblance of the facilities of teaching and without regard to the necessity of such institution, can establish a college of medicine and obtain from the state a charter conveying the privilege of granting the title of Doctor of Medicine. Such colleges must be from their nature mere business concerns, the object of which is, if not actual pecuniary gain, at least the advertisement or prestige which is thought to attach to those who style themselves and officiate as professors.

#### SUPERABUNDANCE OF MEDICAL COLLEGES.

The first bad result which we would expect to flow from such a system as this is the undue multiplication of colleges of medicine. Such is in fact the case. There are, according to the Government Bureau of Education, 151, according to the Association of American Medical

Colleges 170 schools of medicine in the United States. One-half of either number would more than suffice; indeed, if the number were proportioned to the population as in Germany (the country in which medical education is generally conceded to have attained the summit of organization), there would be but thirty colleges in the entire United States, or if, as in Austria, there would be but seventeen. We have, in fact, the largest number of medical colleges in proportion to the population of any country in the world, it being one to about every 440,000 inhabitants. Great Britain, which stands next, has one to about 2,400,000. In Germany it is one to 2,470,000; in Austria one to 5,150,000; in Russia one to 14,400,000.

The most recent statistics bearing on the subject appeared in the educational number of THE JOURNAL, Sept. 21, 1901. In a statement of the distribution of colleges according to population of cities it will be seen that there are ten medical colleges located in towns of less than 10,000 inhabitants, and twenty-four in towns between 10,000 and 50,000. In the report of the individual states it will be seen further, that many of the larger cities have colleges in the proportion of one to 25,000, 30,000 or 40,000 inhabitants. Louisville, Ky., for instance, with a population of less than 205,000, has eight medical schools, almost as many as there are in the whole country of Russia with its 129,000,000.

#### EDUCATIONAL DEFECTS.

The disadvantages of such an over-supply of institutions for medical instruction, distributing instead of concentrating their forces, is too obvious to need to be insisted upon. The number of patients in any given place that can be utilized for clinical demonstration and instruction is limited, and if they must be divided among two or more rival colleges located in the same town, the student will necessarily fail to obtain that comprehensive acquaintance with disease which is one of the indispensable factors in his education. Another tendency, which is the outgrowth of the commercial aspects of our medical colleges, is the admission of unqualified persons to the study of medicine. As the students are the source of income, it is to the interest and is therefore naturally the policy of the colleges to have as great a number as possible. Shortcomings must be overlooked and exceptions made in the qualifications for matriculation, or the rejected candidates will go elsewhere and help fill perhaps the coffers of some rival institution. We do not mean to say that is always or even generally true, but only one of the weak spots, a *locus minoris resistentiæ* of our system of medical education. Justice compels me to add that individuals do arise above these selfish considerations, and I could cite from my own knowledge an instance of a faculty completely submerging its own interest in that of the school and the students, the members thereof sacrificing year after year the financial profits to which each was entitled and contributing their own money as well as their time to the end that the standard of the school might be raised and the benefits to the students be increased. But such disinterestedness and magnanimity of spirit is unhappily not everywhere to be found and ought not to be depended upon; there is moreover something radically wrong in the fact that it should be necessary.

It is estimated that every student in the completion of his course of studies should cost a college not less than \$175, such an amount being that expended by some of the best schools. But in the president's address before the Association of American Medical Col-

leges at Atlantic City last June, it was stated that there were colleges which were turning out doctors at the small cost of \$15 to \$30. There was one college which though it had 531 matriculates, produced the M.D.'s at an average rate of \$27.73 per head. This college reported a net yearly income of \$15,000 over all disbursements. This is an example of what is possible when the faculty does not happen to have the magnanimity of spirit, such as that exhibited in the instance above referred to.

It might seem strange to persons who have not gone to the root of the matter, that medical colleges having for their object instruction in the art of healing and alleviating human suffering—certainly a lofty and humane purpose—should be of all institutions of learning the least endowed. It is only in the past few months that our wealthy benefactors have turned their attention at all to this field. The report of the Government Bureau of Education for 1897 showed that while the 215 sectarian colleges and universities of the United States had together endowments amounting to \$36,500,000, and the 114 non-sectarian ones over \$67,000,000, that the whole amounts of endowments to medical colleges was the paltry sum of \$648,262.

To compare the latter with the other professional schools, the discrimination against the medical school is still no less apparent, for in 1892, eighty-four theological schools reported endowments of \$18,000,000, and seventy-one did not report the item. While of the 151 medical schools, 19 reported a total of only \$906,072. Yet the medical students outnumber the theological by a ratio of three to one. We said that persons considering the ends of medical education and nothing else might think it strange that medical institutions were so meagerly endowed. But it were strange if it were otherwise. Who could be expected to contribute to the support of purely private business concerns, as most of our medical colleges are? One might as well, as Professor Bowditch once remarked, expect the public to endow cotton mills.

The fault here is the same one to which also must be attributed all the other defects in the present system of medical education, which is no other than that they are private institutions and not responsible to the state or any central head. Being independent organizations, they are in many cases without the advantages of university connections, and are thus deprived of that stimulus to high academic aims and purposes, always to be found in the university atmosphere. We may trace to the same vicious system also the fact that the professors and other instructors are not always thoroughly trained scientific men as they should be. They are apt to be more interested in their private practices than in their teaching, and so neglect the latter for the former. They are seldom, as in the European medical schools, teachers first and practitioners afterward, but almost invariably a reverse condition prevails; their primary interests are their private practices. Even when they are men of rare genius and extraordinary mental attainments, unless they happen to be by training, or by nature, especially adapted to the art of imparting knowledge, or if what is worse, though capable, they neglect this sphere of their activities for other interests, it is manifest that the school and the students must suffer.

#### MEDICAL PRACTICE ACTS.

But supposing some will say that all these deplorable things be true as to the condition of medical education in this country, and that it really is very defective and

much inferior to that of other countries and that many incompetent men are yearly graduated, have we not an efficient check and corrective in our system of state licensure to practice medicine? At the present time nearly every state has statutory restrictions in regard to the practice of medicine. Many of these states refuse to accept the diploma, though issued by a regularly chartered college, as sufficient grounds for admission to practice, but have imposed obligations in the form of examinations.

These state practice acts have no doubt shut out many unworthy candidates, have worked in general to the betterment of the profession, and assisted in some measure to elevate the standard of the schools. But when all the disadvantages and defects of the system as now operated are considered, it may be questioned whether the remedy is not as bad as the disease which it is intended to cure. There is no uniformity in the laws of the different states in this matter, but each acting independently of the other, has enacted what regulations it saw fit, and the result has been, there are as many kinds of medical practice acts as there are political divisions in the United States. In a few states all candidates are expected to pass an examination irrespective of the college they are graduated from, or any other circumstance which might be expected to modify the conditions. In other states only those need take the examination who are not graduates of colleges of a certain specified standard and have been possessed of certain specified qualifications before beginning the study of medicine; while still other states except from the examination graduates of their own schools. Certain states require nothing more than the presentation of a diploma from a regularly chartered medical college, while a few others have practically no restricting statutes. Even supposing two states to have, so far as the wording was concerned, in regard to the admission to the practice of medicine, laws that were precisely alike, what guarantee could be given that they would be similarly administered? Especially in the matter of examination there must be the widest diversity; the questions will be different and they would be marked according to different standards; one state board may employ catch questions, the other not; one give credit to style while the other considers only matter; one give an oral, the other only a written examination; one may require clinical and laboratory exercises and operations on the cadaver while the other board confines itself entirely to book knowledge. As an example of the different degrees of severity of state board examinations, the records show that New York and Montana boards reject on an average 30 to 33 per cent., whereas New Jersey, Pennsylvania and Alabama an average of but from 12 to 13 per cent. A uniform execution of the statutes, whatever they may be, is greatly complicated by reason of the differences which obtain in the constitution of the various boards. Provision must be made for the different so-called "schools" of medicine. The graduates of a homeopathic college would not submit to be examined by a board made up entirely of those belonging to the regular "school," nor *vice versa*. In some states we find separate boards, one for each school, while in other states they have mixed boards, made up from representatives from the regular, the homeopathic, the eclectic, or other schools, according to their distribution. These sectional differences in the profession are both a serious obstacle in the way of obtaining uniformity, and are besides the source of irreconcilable disagreements and dissensions.

But why is it we are inclined to lay so much stress on the fact that there is no uniformity in the laws of the states governing the right to practice medicine? What is the disadvantage already referred to which flows from this source? It is simply this: When one state enacts a law *sui generis* in its provisions and which ignores completely licenses to practice already granted by other states, it erects a Chinese wall against all physicians living elsewhere who might desire to change their residence to this state. The inconvenience, not to say injustice, of such a system is too obvious to be argued. There are hundreds of legitimate reasons which may make it to the interest of the physician to take up a residence in a new state. To the recent graduate, an examination in the various branches of medical science may not perhaps have great terrors, but for the practitioner of some years' standing it is like walking up to the pass of Thermopylæ. However wide may have been his experience, however astute he may be in the recognition of disease, or skilful in the application of remedies, or successful in effecting a cure, in ninety-nine cases out of a hundred he will fail to make a passing percentage in the ordinary examination held by the state board for admission to practice.

Of all the various kinds of state practice acts, that which has generally best satisfied the reformers is the one requiring an examination of all candidates. But examinations conducted under such circumstances as have been mentioned, must work great injustice, and though in the existing state of things it is probably a necessary evil, it is a system which ought to be condemned at the same time it is condoned, and be supplanted at the earliest possible day by one that is better. For though they may be conceded to contribute to the correction of some evils, they give rise to others almost as serious. They certainly operate to the disadvantage of a large number of physicians living in all parts of the country and work hardships in the most unmerited quarters. They discriminate against the practitioner in favor of the recent graduate, against skill and experience in favor of theory and speculation, against actual acquaintance with disease and in favor of book knowledge.

But the most flagrant evil resides not in the examination itself, but in the fact that each state and political division, as already remarked, has a method and standard of its own; and for this reason it can not accept the licenses of other political divisions nor in return have its accepted by them. The disadvantages of being without state reciprocity, which the unlike state laws have made so urgently necessary, has been long a thorn in the side of those interested in this subject. Much has been written and many plans have been suggested as remedies. Out of the boards of the different states has been organized a National Confederation of Medical Examining and Licensing Boards, which meets annually in affiliation with the American Medical Association, and the principal object for which it exists and meets, and the principal theme which at these meetings it discusses, is the way and means to bring about reciprocity or interstate endorsements between the different state boards in the matter of licenses to practice. But I feel compelled to say that it is my conviction that the end for which these earnest and enthusiastic gentlemen are striving is almost as illusive as the famed *ignis fatuus* and as far from realization as the dream of Alnaschar. How difficult, if not impossible, it is for any body of men with no authority to enforce their recommendations, to induce all the states to so alter

their statutes on any given subject that they shall conform to some universal standard, when that subject is one in regard to which the states have reserved the right to legislate for themselves, is evident from the fact that though a legal commission, appointed for the purpose of unifying state laws and holding annual conferences, has been in existence since 1892, the progress it has made is comparatively insignificant. The statutes of the different states relating to wills, marriage, divorce, insurance, insolvency, and deeds and other conveyances, though the special subject of this commission's endeavors, and though by reason of their unlikeliness innumerable complications and inconveniences have resulted, still remain for the most part hopelessly irreconcilable. Some of its recommendations as to "law merchant" have been adopted by certain legislatures and it has without doubt attained a certain degree of success in the matter of negotiable notes and the rights and liabilities of those who handle them. But it must be remembered the latter appeal directly to the business interests of the community—which history shows to be always the strongest appeal that can be made—and secondly, those who have labored to secure these results are the lawyers, who, being legislators by training and profession, might be expected to be, as in fact they are, naturally more influential with legislative bodies than any other class of men. Medical men, for some reason which I shall not attempt to analyze, have less influence with the law than any other respectable organization in this country. It is a strange and pitiable truth, that mountebanks, charlatans and ignorant pretenders who are exploiting some new fad or senseless doctrine, have a readier entree at the doors of our legislative halls than have the intelligent and honorable regular members of the profession. Leaving out of consideration, however, all argument based on speculation or theorizing, and judging from results alone, the outlook for a practically operating reciprocity—that is, when every state will be satisfied to merely visé the license which any other state has already granted—is truly discouraging. Dr. W. W. Potter, one of the most active workers interested in this cause, recently said: "The only equitable basis upon which reciprocity can be established that appears both feasible and practicable, is that of equalization of standards of admission to the study and practice of medicine. This implies an equalization of the preliminary requirements of medical students and a uniformity of applying the tests, a uniform period of college training, including uniformity of methods of teaching, and finally an absolute similarity in the methods of conducting state examinations and granting licenses." This statement, by one of the most prominent exponents of the reciprocity idea, sounds very much like a virtual admission of its ultimate failure. Instead of the state boards elevating the schools to their own standard, it appears on the contrary, that improvement in the latter is a prerequisite condition to the success of the boards. Absolute similarity in the methods of conducting examinations must be, from what we have already seen of the organization, character and working of these boards, an impossibility.

#### EDUCATIONAL STANDARD.

We find ourselves then carried back to the proposition with which we started, viz., that to raise the standard of medical education and to advance generally the status of the medical profession, reform must begin in the medical schools. That they are badly in need of reform, I believe we have fully shown, and that under

the present system it will be very slow in coming and can not be complete must be the natural inference. So long as the medical colleges continue to be conducted on a commercial basis, they can be expected only to advance with such degree of celerity as is consistent with their prosperity from a financial point of view, unless an enlightened and awakened public peradventure demand more. But, unfortunately, the ignorance and the apathy of the community in such matters is too widespread and too deeply rooted that much need be expected from this source. Admitting then that medical education in this country has become grounded upon such a system that it can not advance of itself, and that the state boards and the medical practice acts have fallen short of their promises, and it being evident further that the medical profession is powerless either through its press or its propagandists, to accomplish much in the same cause, and that not only does the general public not aid by making liberal endowments but even withholds its much-needed moral support, where shall we look but to the state to rectify the wrongs and supply the deficiencies? The bare suggestion of such a thing will be enough, I know, to cause to appear before the eyes of some the dread specter of paternalism; they will immediately object that the state can not properly concern itself in such a cause; that medical education is the education of only a limited class of citizens and does not directly benefit all taxpayers; and they will say that if the state support any education at all it must be only that of the most broadly generalized knowledge, such only as is needed to prepare the young as they grow up for the duties and privileges of citizenship. Far be it from me to urge the adoption of a policy that in the smallest measure transcends constitutional limits or that involves a departure from cherished republican principles and traditions. But it is not true that in the past our government has supported primary and secondary education alone and that it has refused aid to higher education and to specialized branches of science and technical studies. By grants of land and money Congress has contributed millions of dollars to colleges and universities for the latter purposes. According to the report of the Bureau of Education for 1897, there has been annually appropriated by the central government for instruction in mechanical arts and agriculture, a sum equal in 1897 to a capital invested at 4 per cent. of \$26,400,000. In addition to this, it has created under the Hatch bill the so-called agricultural experimental stations in each state for promoting the study of agriculture, appropriating therefor a sum which capitalized at 4 per cent. would amount to \$18,000,000. We take the ground (confident of its being a tenable one) that Congress can just as consistently contribute to institutions for the education of the physician, as to those for the education of the mechanic or the farmer, and we might add with far greater reason. There is truly no trade or profession in which the community is so vitally concerned as that of medicine. There is none, in fact, which exercises so wide and such a profound influence upon our national growth and development. Healthy men are necessary to a healthy state as the *corpus sanum* to the *mens sana*; and unless the physical well-being of its citizens is cared for, we may certainly expect national decay and degeneration to follow, if not eventually the utter dissolution of the very elements of the civic organism. This was understood as far back as the day of Lycurgus, and the wise legislator and statesman of the present era can not afford to ignore it.

## NATIONAL AND STATE SUPERVISION.

There are some special reasons why the state ought to be interested in the education of those who practice the healing art that apply to no other calling, profession or class of citizens, however much it may contribute to our national greatness and glory. It is peculiar to the medical profession, owing to the immature development of the science upon which it rests, the great number of undemonstrated assertions and of unsolved problems of its practice, and of the absence of logical criteria by which to judge them, and of its being in consequence a profession of empirical methods and practices, that it is impossible for the laity to form any just idea as to the merits of those who follow it. In the case of any other of the occupations, we are able to judge directly from observation or from results, whether that which it furnishes is the same as that which it is represented to be or not. Every one may know sooner or later whether he has been deceived into buying unwholesome food, or a machine that will not run, but who can tell whether a certain disease which a physician has been called to treat would have gotten better or worse without his drugs? Any conclusion drawn from a single case is unreliable; the *post hoc ergo propter hoc* leads as often to false as correct deductions; and even though we could tell from results, think how serious may be the results! One may be willing to prove the pudding by tasting it, but no one could wish to go to sea in a vessel whose seaworthiness is in doubt. Some persons, as previously mentioned, are guided in their judgment of a physician by entirely extraneous circumstances, such as the extent of his clientele and his display of wealth, etc. If this were a fallacy to which only the ignorant and uninformed are liable, I should hardly mention it. But persons, otherwise very intelligent, are not altogether free from the same error and are hardly less often misled.

When it is considered that the physician is one in whose hands is placed our most precious heritage, our health, and that our life and happiness are at his mercy, it would be only natural if we were disposed to demand some guarantee of his capability. One may say that he is willing to assume the responsibility of his own judgment and that he asks no other guarantee. Nevertheless, it must be admitted, there are thousands who suffer because of malpractice, and moreover, there are occasions such as when residing temporarily in some strange town or place, or in the case of emergency, when the ordinary requisites to forming a safe judgment are lacking.

Another reason why the physician's education should be the concern of the state is that he is by implication, if not by legal enactment, in the pursuit of his vocation, an officer of the state. The community has come to look upon him as a public servant who is obliged to attend the sick, to relieve suffering, and at any loss to himself to attend contagious diseases, and give up his time and his services to the indigent sick or those who have been accidentally injured. That the profession has accepted this interpretation of their duty is evidenced by the hospitals, dispensaries, and other charitable institutions, to which it is a part of their faith to give their services without pay, for the benefit of the deserving poor. To understand to what degree the profession has taken upon itself the welfare of the community, read Paragraph 1, Article 1, of the Code of Ethics adopted by the American Medical Association, which is as follows:

As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession, as on subjects of medical police, public hygiene, and legal medicine. It is their province to enlighten the public in regard to quarantine regulations, the location, arrangement and dietaries of hospitals, asylums, schools, prisons and similar institutions; in relation to the medical police of towns, as drainage, ventilation, etc., and in regard to measures for the prevention of epidemic and contagious diseases, and when pestilence prevails it is their duty to face the danger and to continue their labors for the alleviation of the suffering, even at the jeopardy of their own lives.

Perhaps someone will say that this lofty position which the medical profession has taken, while very laudable and creditable to the profession, the state can not take official cognizance of, because it has come about through no legislation, and if the physician be a guardian of the public health, etc., he is entirely a self-constituted one. In reply, it may be stated that there are numerous instances of the courts adjudging physicians just as though they were *de facto* officers of the state and responsible to it for acts which in other professions would be left to the individual inclination; and of their being punished not for some overt act of malpractice, but for carelessness and neglect in the practice of their profession. In other words, when once he has adopted the healing art as his life work, the physician is not permitted to remain even passive, but he must relieve the sick and attend the injured and go when called by anyone who may be suffering, whether it shall happen to be to his own interest or liking to do so or not.

Finally, it might be urged as a justification of the interference of the state in the matter of medical education, that it is called upon to do so in the interest of equalization of competition, one of the acknowledged administrative functions of government. The state, though it does not directly grant it, legalizes the title of M.D., and as we have just seen, it exacts of the practicing physician unusual obligations. Would it be more than just, therefore, did the state take such measures as were necessary to give specific meaning to the title, and see that only those should possess it who have earned it; that the man, in other words, who has fraudulently won the degree should not be placed on equal footing with him who has given up years of his life to a serious study of his profession. We hold it, therefore, to be the rightful business of the state, first in the interest of the community, and secondly, out of justice to the class concerned, to educate or at least take a part in the education of the physicians and surgeons of the country.

The United States has established and maintains schools in which are trained, at great expense to the government, soldiers who fight the enemies on land and sailors to contend with those on the sea, but not one cent has it ever contributed to the training and education of a class who have to contend with the omnipresent foe, in the shape of death and disease, far more destructive, because clandestinely and incessantly at work. But let us be more specific and consider how it would be possible to carry into effect any plan for the betterment of medical education by state interference.

It would be useless to have the different states undertake the control of medical education within their limits, for the lack of uniformity of which we have said so much, which is the bane of the present system, would in nowise be improved. Each state would prescribe a different curriculum just as at present each state has:

different statutes regulating the practice of medicine. Yet the general government can not constitutionally undertake it. As is well understood, the general government has only such powers as have been delegated to it by the state and education is not one of such. This is one of the police regulations reserved by the several states as their own right, which, therefore, they jealously guard and are unwilling to surrender.

Without entering at all upon the question of the wisdom of such an arrangement, or attempting to decide between the conflicting interests of state and central government, we see no reason why the two might not enter into an agreement whereby the latter could attain its object without encroaching upon the rights of the former; why Congress could not appropriate a sufficient sum to be applied to medical education in each state, leaving to the states entire control thereof, and only stipulating as a condition, that a certain standard uniform throughout shall be maintained and (this is the important feature) that the graduate of the college should be allowed to practice without further examination in any part of the United States. Such appropriation might be applied to the state universities or to some other already existing college of medicine.

There have been for some years established throughout the United States so-called agricultural experimental stations, supported by the general government yet managed by the state. They have worked generally smoothly and have accomplished much good. We believe that a scheme of this kind applied to medical colleges would in a short time eradicate all the evils of our present system of medical education.

It would tend at the same time to advance the standard of the schools and to lessen their number and to render them uniform throughout the United States. As many of the states at present require all candidates to pass examinations, it is evident that those colleges whose graduates were entitled to practice in any state without undergoing these examinations, would have a great advantage over all others. The inferior institutions would necessarily go to the ground in a competition wherein they were so heavily handicapped. But there is no reason why the best class of schools should not continue to exist and thrive, even though they failed to obtain this particular state favor. Some are already so abundantly endowed and so well situated for giving clinical instruction, or have instructors and professors of such fame, that the students will be attracted thither in preference to the national college. Some would no doubt drift into the position of preparatory schools where the student can study more conveniently for a season or so, finishing only at that school which gives him the right to practice along with his diploma. But in order that it shall succeed in this capacity, it would have to model its curriculum after that of the state school, so that its students could enter the next class there without difficulty. Thus the state school would operate to bring about a uniformity in all schools, so that, sooner or later, we might have in the United States the same condition of things as at present exists in, for instance, Austria or Germany, where it is the custom for the student of medicine to divide his course of study among two or more schools in different parts of the country. It is possible, too, that under the system we suggest, certain institutions would become famous for certain special branches of medicine, as bacteriology or experimental medicine, and that some which are now giving a full course of study, would become post-graduate or polyclinic schools, to which students would

resort who wished to get increased clinical experience or to devote themselves to some special department of medical science.

In the course of this paper we have seen fit to institute certain comparisons which were intended to show that although we had made certain gains, the condition of medical education was still many steps in the rear of that of the countries of Europe. As the day seems now to have come when we no longer think ourselves too mean to be measured by an international standard, it seems to me that this comparison ought to have some force.

We have heard a great deal of talk lately about our financial system and of our standard of money; and we heard it urged on one side that we should have a money system that could stand alone and get along without the help of other nations, and on the other side, that we must have a standard that was good the world over, that would be accepted by any nation under the sun. We come now to appeal to the medical profession and to the people at large (who in fact, after all, are they who are most vitally concerned) that they shall adopt as broad views upon the subject of health as upon that of wealth; and that they shall not think more of dollars than they do of doctors; that they shall never cease their efforts until we have a system of medical education and a standard equal to the best, and until the products of our institutions, stamped as they are with the seal of government authority, shall no longer be discredited and regarded as spurious coin abroad, but shall pass current in any, even the most enlightened countries of the world.

#### FURTHER REPORT OF A PREVIOUSLY RECORDED CASE OF BLASTOMYCOSIS OF THE SKIN; SYSTEMIC INFECTION WITH BLASTOMYCES; DEATH; AUTOPSY.\*

JAMES W. WALKER, M.D.

Adjunct Professor of Medicine, College of Physicians and Surgeons.  
WITH INTRODUCTORY NOTE BY THE ORIGINAL REPORTER.

FRANK HUGH MONTGOMERY, M.D.

Associate Professor of Dermatology, Rush Medical College.  
CHICAGO.

#### INTRODUCTORY NOTE BY DR. MONTGOMERY.

I reported this case before the meeting of the American Dermatological Association in 1900<sup>1</sup> as a case of blastomycosis of the skin (blastomycetie dermatitis of Gilchrist), in which death finally occurred from miliary tuberculosis of the lungs and other organs. In explanation, I would state that I was away from Chicago during the last weeks of the man's illness and at the time of his death. My friend, the late Dr. D. D. Bishop, in whose charge I left the case, wrote me that the autopsy showed the man died of miliary tuberculosis. Up to this time the diagnosis of the cutaneous lesions had not been definitely determined, though they had been carefully studied both clinically and histologically by a number of competent observers. The case was now considered an unusual form of cutaneous tuberculosis followed by systemic infection. I gave Dr. Bishop the privilege of reporting the case in full, but unfortunately, Dr. Bishop himself died before completing the work.

In January, 1900, Dr. Hyde and I had several cases of cutaneous blastomycosis under observation, the clin-

<sup>1</sup> Transactions for 1900; and Jour. Cut. and Gen. Urln. Dis., January, 1901.

ical features of which suggested to us this old case. On inspecting my old slides of the case, I found characteristic organisms present in such large numbers that it is difficult to understand how they escaped the observation of the several pathologists to whom the slides had been shown four or five years before. I attempted to find the hospital and postmortem records, but these records could not be found. Several workers in the laboratory, however, remembered the case very well and assured me verbally that there was no question that the man had died of tuberculosis. One of these men, who was particularly interested in the case, stated he knew positively that guinea-pigs inoculated with the tissue had died of generalized tuberculosis. As after carefully searching several hundred skin sections I had found four or five bacilli which morphologically and in staining properties were identical with tubercle bacilli. I did not hesitate to accept the postmortem findings as reported to me. These few bacilli were, as I reported, found in a small abscess communicating with the surface of the skin and were undoubtedly the result of secondary infection. Such infection could easily occur in a moist fungous surface which had been exposed to the air for many months. I was satisfied (as were also Dr.

cutaneous blastomycosis has been followed by systemic infection with blastomycetes. (In the Busse-Buschke case<sup>2</sup> the cutaneous lesions were accompanied, if not preceded, by symptoms of chronic pyemia). For seven years the disease was limited to a single area on the skin and the man's general health was unimpaired. About eight months before he died, he began to have attacks of chills and fever, lasting four and five days, followed by the appearance of subepidermic swellings, some of which developed characteristics identical with those of the original lesion. Dr. Hyde, who followed the case carefully, believes with me that these manifestations marked the beginning of systemic infection. It is highly improbable that the new lesions were due to auto-inoculation through the skin, for the following reasons: They were preceded always by a marked systemic disturbance; they were distinctly subepidermic, the skin remaining unbroken until after the swellings subsided; they showed no central point where the inflammation (always subacute in type) was more intense, or where there was any clinical evidence of suppuration or necrosis; and, finally, during most of this period the cutaneous lesions were kept covered with antiseptic dressings, reducing the danger of auto-inoculation through the skin to a

Figure 1.

Figure 2.

Hyde and others who had watched the case carefully) that this was a case of blastomycosis of the skin followed by secondary infection with tuberculosis.

After reporting the case, I learned that Dr. Walker had been associated with Dr. Bishop in working it up and had himself made the postmortem.\* Dr. Walker's sections of lung tissue are full of typical blastomycetes, while diligent search on his part failed to discover tubercle bacilli. The evidence now presented by Dr. Walker shows conclusively that there was systemic infection with blastomycetes. There is no positive evidence obtainable of any tubercular infection aside from the few tubercle bacilli which I found in the cutaneous abscess. Moreover, the clinical history (see the previous report),<sup>1</sup> not only of the cutaneous affection but also of the early constitutional disturbance, and the manner in which metastases occurred were unlike those of tuberculosis.

This case is then of special interest because of its being the only case yet reported in which an undoubted

minimum. (See original report<sup>1</sup> for details.)

The clinical histories of this case and of the one reported by Busse and Buschke,<sup>2</sup> together with the culture and inoculation experiments of Ophüls and Moffit,<sup>3</sup> suggest strongly a close relationship between, if not the identity of, cutaneous blastomycosis and the cases of protozoic dermatitis reported by Gilchrist, Rixford, and others.

#### DR. WALKER'S REPORT.

C. W. T., aged 33, carpenter, admitted to Cook County Hospital in August, 1894, and remained two weeks, and was again admitted in March, 1895. Father died, aged 64, of heart disease; mother at 36 of consumption. Two brothers living and in good health; one died at 36 of heart disease. Three sisters living and well; none dead. Patient has been married 10 years; has had 6 children, 4 of whom are living, and in excellent health. He is a large, well-proportioned man, and has always been unusually strong and vigorous. No evidence of disease other than that of the skin can be found. No history nor evidence of syphilis nor of tuberculosis obtainable. Seven years previous to his first coming to the hospital, while wearing

\* I also learned that the photograph I published had been taken by Dr. Walker. I had several photographs of the man and on selecting one for publication failed to recognize it as the one sent to me four years before by Dr. Bishop.

2. Virchow's Archiv, 1895, cxi, 23, and Verhandlung der Deutsch. Dermatolog. Gesellschaft, 1899.

3. Philadelphia Medical Jour., 1900, v, 1471.

a new woolen shirt which irritated his skin, he scratched himself and caused bleeding. The resulting lesion became covered by a crust, which when removed would reform. It slowly increased to the size of a silver dollar, then remained stationary for three years, then increased again. Medicines internally and local applications have been tried without limit and without avail. Patient says the lesions are practically painless, but tingling and smarting are occasionally felt. About October, 1894, the process began under the right eye, and in January, 1895, on the left temple, and in each place has spread rapidly. Has been able to continue working until July, 1894.

*Present condition, March 8, 1895:* Patient is fairly well nourished, heart and lungs are negative, pulse, temperature and respiration normal. The extent and location of the cutaneous lesions are indicated by the photographs. They consist of a verrucous tissue of purplish color, elevated at the highest points about one-half an inch above the normal skin. The tissue is soft, friable and spongy and pus can be squeezed from beneath it in droplets. Surrounding it is a purplish-red zone, about one-half inch wide, of normal texture. Toward the left side of the lesion on the back are a few patches, dry, smooth, but irregular and pink, where a thick, firm, scar-like tissue has formed. Scattered over the back, without any regular arrangement, but mostly on the right side, are a dozen or more nodules to be felt in the skin as firm bodies, slightly projecting, red in color and shading off gradually, the largest being the size of a small pea. They are tender on pressure and not ulcerated.

*Operation:* On March 16, eight days after admission to the hospital, under chloroform anesthesia, all the spongy tissue on each side of the face was curetted away and the base of each ulcer cauterized with the Paquelin cautery. Wet boracic-acid dressings were then applied daily. Previous to the operation, the temperature was 98.6, pulse 72 and respiration 20. Nine days after the operation, the two areas presented clean granulating surfaces and were then covered with Thiersch's grafts, furnished by a friend of the patient. Up to this time the patient had shown no ill effects of the operation, but on the day of skin-grafting his evening temperature was 100.2, pulse 82, respiration 20. After this time, pulse, respiration and temperature were always above normal.

April 3, nine days after skin-grafting, eighteen after curetting: Union of grafts complete, dressings discarded. There is a row of new tubercles at the lower edge of the lesion on the right side of the face and one tubercle on the upper eyelid. Patient perspires profusely. Most of the spongy tissue on the back has disappeared, leaving large patches that have a smooth, red, moist surface. Margins are as before. There appears to be a slight dulness on percussion over the right upper lobe. No râles nor bronchophony. There have appeared a number of red papules, scattered over the back, firm and tender to touch. Urine negative.

April 8, twenty-three days after curetting: Each of the three smaller lesions on the back are now surrounded by a sharply-defined, narrow furrow, as though caused by pressure with the edge of the finger-nail. On the margin of the large lesion this phenomenon is seen only in places. Appetite continues to fail, emaciation is marked, temperature 102, pulse 120, respiration 36.

April 11: The papules on the back are breaking down. The periphery of each is marked by the gutter-like line above described. Dyspnea very marked; ophthalmoscopic examination negative; no tubercle bacilli in the sputum. It is worthy of special note that under no more aggressive treatment than daily wet boracic-acid dressings, the large fungoid area on the back became a clean, though rather soft, granulating surface, the mass seeming to melt away. The margin, however, appeared to be unaffected by this treatment. In view of Dr. Nicholas Senn's diagnosis of tuberculosis, in which Drs. Hyde, Montgomery and Bishop were then inclined to concur, the incidence of post-operative dyspnea and associated symptoms naturally suggested the diagnosis of acute general miliary tuberculosis, which the subsequent course tended to confirm.

April 18, thirty-three days after operation, his wife took him home, where I continued to treat him. He died about ten days

after removal, forty-three days after operation. I was permitted to make an autopsy, but was limited to an abdominal incision of about four inches. Through this I removed pieces of the lung, liver, spleen and kidney, all of which were studded with miliary bodies, the lung surfaces being entirely covered by them, a finding which I erroneously concluded to be confirmatory of the diagnosis of acute general miliary tuberculosis, secondary to a cutaneous tuberculosis.

#### THE HISTOLOGIC EXAMINATION.

Repeated microscopic examinations of sections of the skin removed from the progressing margin of the lesion at the time of operation, which were made by Drs. D. D. Bishop, A. F. Lemke and myself, failed to demonstrate tubercle bacilli. This negative result, however, did not greatly disturb my allegiance to the diagnosis of tuberculosis, because those who had sought tubercle bacilli in cutaneous tissue by the methods then in vogue testified to the exceeding difficulty of finding them. It seems

Mr. Ready's. I did not know that Dr. Montgomery had recognized the nature of the case until after he reported it. I regret exceedingly not now being able to find tissue from the autopsy on this patient other than that from the lung, the other specimens having been lost.

#### REPORT ON PATHOLOGY.

We are indebted to Dr. Leo Loeb for the following report on the pathological histology of the lung:

"1. The lesions are distinctly nodular. The alveoli between the miliary nodules being normal or showing only slight pathological changes.

"2. In the nodules are the following changes: Most characteristic is the connective tissue proliferation, which in some places has so far advanced that fibrous nodules are formed. Connected with some of these fibrous nodules, we see areas of different sizes where the alveolar structure of the lung is still more or less pre-

Fig. 3.—Same field as Fig. 4. X 250.

Fig. 4.—Section of lung, showing blastomycetes, some of which are budding. X 600.

to me, as it has to others, more than probable that some of the cases that have resulted in failure to find tubercle bacilli have been instances of blastomycetic dermatitis. The same explanation, perhaps, accounts in some degree for the polymorphism alleged of cutaneous tuberculosis.

Fragments of tissue removed at the time of operation were used to inoculate two guinea-pigs. Nodular masses developed the size of a pigeon egg with the skin adherent over them. In fourteen days the mass in one animal ruptured and discharged a caseous plug, which resulted in recovery. The other died in twenty-three days, the autopsy revealing nothing but a similar, though firmer caseous mass at the site of the implantation.

I first suspected what proves to be the real nature of this case after reading the Owens-Eisendrath-Ready reprint and was convinced by comparing my slides with

served and the alveoli are partially filled with a granular material, partially with masses resembling fibrin, besides a variable number of mononuclear cells; but in the majority of the alveoli the connective tissue begins to grow into these masses.

"3. Some alveoli are filled almost entirely with cells resembling alveolar epithelial cells. Polymorphonuclear leucocytes are seen in places, but they are not present in large numbers.

"4. Necrotic areas occur occasionally in and adjacent to the fibrous nodules.

"5. Location of organisms: *a*. We find these only in the foci showing pathological changes, not in the alveoli that lie between these foci. *b*. In these foci we do not find the micro-organisms distributed equally

everywhere, but the large majority of them we find where connective tissue has been developed or is just developing. There are relatively few in the alveoli that contain only granular or fibrinous masses with a few cells. There are some areas several times the size of an alveolus which are almost filled with masses of the micro-organism. Such areas are found especially in the neighborhood of the larger vessels and bronchi. In the necrotic portions of the fibrous nodule we also find the remains of the organisms. *c.* Where large masses of the organisms are studded together, we see only little fibrillar material between, and the connective tissue distinctly invades these masses only at the margins. In other places where the organisms are less numerous, we find connective tissue frequently surrounding little heaps of them and penetrating some of the heaps. Individual micro-organisms are frequently surrounded by a layer of flat connective tissue nuclei. The organisms are often enclosed in giant cells, both in the fibrous nodules and also in the alveoli into which connective tissue penetrates. The situation of the micro-organisms in the giant cells varies. Sometimes they are at the periphery and the nuclei of the giant cells are in the center. Sometimes this order is reversed. Occasionally we find them enclosed in one large cell.

"6. We also find changes occurring in the organism itself. Usually it has a darkly staining center, taking up the nuclear stains. In some specimens stained with methylene-blue the peripheral part around the nucleus-like body shows many fine blue granules. In some organisms the central body takes up the stain only slightly or not at all. Occasionally we see budding organisms. Other organisms are seen with a central round body having a mulberry-like appearance with the segments of equal size. This appearance suggests the possibility that segmentation (sporulation) is taking place. But it is more probable that this is a change comparable to one not infrequently found in certain nuclei. No definite statement, however, regarding this can be made. The organism is normally variable in size. Further changes are the presence of very large bodies, whose diameter is two to four times as large as the ordinary ones. These usually do not show any special structure and are probably swollen degenerated forms.

"7. We see, therefore, that at this stage of the infection this micro-organism does not cause any tumor-like formation in the lung, not even an epithelial proliferation similar to the one found in the skin, but changes of an inflammatory character comparable to those found in tuberculosis of the lungs."

#### DISCUSSION OF OTHER CASES.

In operating in the manner I did, I acted upon eminently responsible surgical advice and in uncertainty as to the exact pathology. I now believe that this method is attended with too much risk of general dissemination of the pathogenic organisms to warrant its adoption. Lassar, speaking of the treatment of these cases—regarding them, however, as tuberculosis—insisted very emphatically on a bloodless operation—the Paquelin cautery. Caspar and Gilchrist say:<sup>4</sup> "We had intended to place the patient under the influence of ether and curette the cutaneous lesions very thoroughly and then apply the nitrate of silver stick." The patient left the hospital and this was not done.

In 1895 Otto Busse published a case in Virchow's Archiv: A woman upon whose tibia a swelling ap-

peared, which was cut down upon eight months later by Helferich, an abscess cavity evacuated, and the abscess wall removed, together with the anterior edge of the tibia. Lesions of the face, neck, right ulnar and sixth left rib followed. The patient died five months after operation and the autopsy revealed numerous foci of disease in the bones and internal organs, from all of which the blastomyces could be cultivated.

Drs. Hyde, Hektoen and Bevan say:<sup>5</sup> "The propriety of removing all the morbid tissue with the curette was discussed." It healed, however, under the administration of potassium iodid. Rixford and Gilchrist<sup>6</sup> publish a case of protozoan infection, which began in 1886, and in 1894 all the infected areas, save one, were "most thoroughly scraped with a sharp spoon and 1-500 bichlorid applied." Cough developed, with purulent expectoration. Fine moist râles were general over the chest and it was thought that the patient had contracted tuberculosis. Death occurred ten and one-half months after operation, protozoa being found in most of the organs and lymph glands, being more abundant in the lungs than in the skin. Microscopically and macroscopically there was a strong resemblance to tuberculosis, but no bacilli were found. This case is here referred to because of general dissemination following within a few months the use of a curette on a skin lesion which had existed for eight years without constitutional disturbances.

I have cited these cases because of their relation to treatment and its results. Drs. Hyde and Montgomery are of the opinion that in the case here reported systemic infection was present prior to operation, as evidenced by the chills and fever, and by the manner in which new lesions developed at a distance from the original one. This is quite possible, and still the curettage may have hastened the termination of the case.

The value of large doses of potassium iodid, first noted by Dr. Bevan, has been demonstrated by a number of observers. In practically all cases it has produced marked improvement, and in several instances it has apparently caused a complete disappearance of the disease. Failing in medical treatment, the actual cautery or free excision with deep dissection and repairs by skin grafts or plastic operation should be the method of election and the curette eschewed as being fraught with too much danger.

## A SERVICE VIEW OF HERNIA.

ITS PREVALENCE AMONG OUR TROOPS IN THE ORIENT.

E. F. ROBINSON, M.D.

KANSAS CITY, MO.

With the exception of gunshot wound, hernia is the commonest surgical condition that confronts the military surgeon in the Philippines. Among our troops in the Orient it develops as a tropical disease, and is now a condition to be reckoned with just as much as dysentery or typhoid fever. For while it rarely kills, it incapacitates. It puts men out of action, and so out of the service. With the immediate increase in our standing army and the thousands of raw recruits that will soon be ordered to foreign service, the importance of this subject will be greatly augmented, consequently the consideration of the question may not be *inappropos* at this time.

Unfortunately, there are at hand no definite statis-

6. Johns Hopkins Hospital Reports, vol. 1, 1896.

tics which will show the percentage of hernias among our troops in the tropics; but a very correct estimate of the prevalence of this surgical condition may be deduced from the fact that up to May 15, 1900, 229 cases of hernia were seen by the writer alone in the military hospitals in Manila. These cases also, it must be remembered, were among a most carefully selected class of men, in whom the existence of hernia had been absolutely excluded at the time of enlistment.

The reason for this remarkable tendency to the development of hernia among American troops in the Orient can be attributed directly to several important general and local causes. In the first place, great and sudden loss of flesh is the early experience of more than 90 per cent. of Europeans in the tropics. To a certain extent the climate is directly responsible for this. One eats less and perspires more. Intermittent or persistent attacks of diarrhea, dysentery or typhoid fever, and kindred wasting diseases—for few escape some illness in the first few months of tropical service—all tend to lessen the bodily weight. General relaxation or loss of muscular tone is an important factor. This is evidenced by the great frequency of hemorrhoids, varicose veins and varicocele which appear among our troops in a hot country. Added to this the great and sudden strain to which the soldier is subjected in an active campaign, and the most favorable conditions are produced for the development of hernia.

#### INFLUENCE OF THE ARMY CARTRIDGE BELT.

But the chief causal factor, it is believed, lies in the army cartridge belt. One hundred and fifty to two hundred rounds of ammunition is no small load when added to the rifle and equipment of an infantryman. When this weight is thrown around the abdomen and only supported by its constriction above the hips, scarcely a muscular movement can be made without undue pressure on the lower abdominal wall. The belt may not be tight, yet it constricts. For some unaccountable reason the American is fond of a belt, and notwithstanding its weight, the soldier will often hang his canteen, meat can and extra pair of shoes and provisions to it. The regulations require that the belt shall be worn at a certain place about the abdomen. This and habit are absolute. Even in "route marching"—except when carrying extra ammunition—the cartridge belt is seldom swung from the shoulders. In almost every army except our own the deleterious influence of the abdominal cartridge belt is recognized, and so discarded. The Spaniards have an excellent cartridge bag or pouch in which the weight hangs from the shoulder, and is kept from flopping by a loose belt about the waist. Our own marine corps had an excellent hygienic arrangement for ammunition for the Lee rifle, by which the weight of the belt hung from either shoulder by suspenders, thus evenly distributing the burden and not infringing upon the abdominal wall.

In addition to being a fruitful cause of hernia, the regulation belt is not particularly efficient or accessible, and much ammunition is lost from it. On one occasion during a "hike" the author picked up a campaign hat twice full of cartridges which had fallen from these belts while a company was advancing less than one hundred yards. It is earnestly hoped that some more efficient and sanitary means of distributing the soldier's load will be devised with the development of the new uniform.

From Aug. 1, 1899, to May 15, 1900, at the First and Second Reserve Hospitals, Manila, 104 cases of hernia

were operated on. Of these operations 53 were performed by the author while serving as chief operating surgeon, and of them complete records are at hand. The remaining 49 were inguinal hernias. In 27 the operation was that of Bassini, and in 22 its character was unknown. There is no record of the result in these early cases.

Of the author's 53 cases, 45 were inguinal, 31 occurring on the right side and 14 only on the left. There were two femoral and six ventral hernias among the total number. The operation performed was that of Bassini in 43 cases. The method of Halsted was followed in 2 instances, but one of these cases developed a painful testicle later. Of the 2 femoral hernias, one was a large omental hernia about the size of an orange. The contents of the sac were much thickened and presented a peculiar "coxcorn" appearance, suggesting malignancy, but the microscope failed to bear out this opinion. The other case contained a knuckle of small intestines. In both, the canal and ring were closed, after the manner of Bassini's treatment of femoral hernia. Two cases of inguinal hernia contained undescended testicle; in one instance castration was performed, and in the other the organ was anchored to the base of the scrotum, with a most satisfactory result. Primary union resulted in all but one of our cases, and this the first case operated on. In this case, infection was traced unmistakably to the Kangaroo tendon used. Upon having all of this material resterilized no further difficulty was encountered. In all our cases buried sutures of this material were used, while the hernial sack was transfixed and ligated with fine silk. Sutures of silkworm gut closed the skin wound. In our early cases the mattress suture of Kangaroo tendon was used, but ultimately abandoned for the continuous suture. The advantage was threefold: 1. Less knots were left, and so less material to be absorbed and to run the risk of receiving or causing infection. 2. The tension on the sutures was less and was more evenly divided, and there was less danger of splitting Poupart's ligament, with the consequent tearing out of the sutures. 3. Much less time was consumed in the operation. This latter, while not so important a consideration in a temperate climate, is one that must always be reckoned with in the tropics.

For some reason, probably the general low muscular tone and the reduced vital condition of the patient, surgical shock was a much more common occurrence in the Philippines than in the United States. Especially was chloroform badly borne. Shock seemed more profound after its use; although great care was exercised, alarming symptoms again and again developed, and death resulted in three or four instances. Finally, the use of the drug was almost completely abandoned. Our own experience with chloroform was very similar to that of the English surgeons in India, where ether has almost completely replaced it.

#### WISDOM OF EARLY OPERATION.

The question of the wisdom of operating on these cases of inguinal and femoral hernia, I believe, should be unqualifiedly answered in the affirmative: Most certainly, operation, and operation early, or discharged from the service. Recurrence is rare, indeed, after the improved surgical operation of to-day, and particularly so in men as strong, young and vigorous as those that come to operation in our military service. Unfortunately, a sufficient length of time has not yet elapsed to determine definitely the permanency of cure in our

cases; but now after six months—the latest date from which we could secure information—not a single case of either inguinal or femoral hernia operated on is known to have recurred.

Ventral hernia, however, is by no means so amenable to treatment. Of the 6 such cases operated on, 4 were in the scar of old appendix operations, and 2 occurred just above the umbilicus in the median line. Within two months after operation recurrence had occurred in 2 cases; the ultimate results in the others are not known. From the standpoint of efficiency to the service it is extremely doubtful whether operation on these cases is justifiable. Surely a man with any tendency to weakness of the abdomen should not be enlisted. Even a solid "appendix scar" should bar him. In general, indeed, it may safely be said that discharge is preferable to operation in cases of ventral hernia. From our own experience and that of other military surgeons we are led to conclude that early radical operation should be performed in every case of inguinal or femoral hernia, and we firmly believe that thus many additional years of trained service will revert to the improvement and efficiency of our standing army.

#### CONCLUSIONS.

1. Additional care should be exercised in the enlistment of men with absolutely sound abdominal walls, and they should not be over weight.

2. Regular exercise should be insisted upon with troops in the tropics, even during so-called "field service," that the general physique may remain above par. There is too great a tendency among officers and men in a tropical country to relax all form of physical exercise and to think because they are in the field such is not necessary.

3. The discarding of the old abdominal cartridge belt and the substitution in its place of some form of belt, if necessary, by which the weight is swung from the shoulders and the abdominal muscles are not restricted.

4. General attention to hygiene and the avoidance of the causes of disease in general are, of course, important factors in preventing hernia.

5. Early operation in all cases of inguinal and femoral hernia.

#### HYPNOTICS—THEIR USE AND ABUSE.

ARTHUR W. ROGERS, M.D.

WACWATOSA, WIS.

In a recent paper<sup>1</sup> Dr. Church and Dr. Hutchinson called attention to the untoward and even fatal results of the prolonged and excessive use of trional and sulphonal. It is true, as they state, that "during the past few years both the profession and the laity have been using sulphonal and trional in the most reckless manner, due to the widespread belief that the employment of these remedies is comparatively without danger."

It is my desire to seek further into the causes why a belief fraught with so much danger has become so prevalent and to call attention to further instances where the above mentioned as well as other hypnotic and sedative drugs have been abused, both by patients and in some cases even by practitioners.

It seems to us, in considering the causes why individuals are so prone to excess in the use of hypnotic drugs, that there are several factors. It is not to be expected that patients should fully realize the dangers attached to such excess. Their one idea is to secure relief from

the distressing insomnia and oftentimes they act upon the trite fallacy that "if a little is good, more is better." All these drugs are alike in the one respect that their potency gradually fails, leading to increased dosage. It is less expensive and less troublesome to call on the apothecary for a new supply than to consult a physician. Consequently the original prescription may be refilled many times and the patient may be all the time laboring under the error that his insomnia is being cured. This misfortune can be obviated only by the physician taking the precaution to properly instruct his patient and to mark his prescription in such a manner that they can not be refilled indefinitely. The prevalence of insomnia is an incentive to the altogether too enterprising manufacturing pharmacists. New hypnotics are constantly being presented to the profession and samples scattered broadcast. These new drugs are mostly "harmless" and are used indiscriminately before being given a proper trial and before they are endorsed by reliable men. The ease with which this class of drugs can be procured is alarming and in some places has called forth measures regulating their sale. The above-mentioned facts make it very apparent that it is the duty and privilege of the medical profession to regulate the existing evils connected with the dispensing and use of hypnotic and other dangerous drugs.

In the entire category of diseases we find none in which insomnia is the symptom *par excellence* as in nervous and mental maladies, and too, it is right here that the hypnotics are chiefly abused. Because of the slowness of the nervous system to respond to treatment there is opportunity for prolonged and continued use of these drugs and even danger of forming the "hypnotic habit." It is the neurasthenic patient that too often perseveres at his task while using hypnotics each night to produce the sleep that he otherwise fails to get. Again, when the busy practitioner is called in to see a patient who has not been sleeping or who is even excited and violent, the first thing he proceeds to do is to relieve these symptoms, and, other measures failing, the hypodermic and hypnotic is called into requisition. Chemical restraint is often found necessary for such a length of time that toxic symptoms warn him that the danger point has been reached. It is to this class of patients that I wish to call attention and illustrate briefly with a few cases.

It seems to us that the matter of idiosyncrasy is too often lost sight of in prescribing hypnotics. We have all witnessed the unexpected and undesirable manifestations when exhibiting such drugs as morphin, quinin, iodids and many others in certain of our patients. Why should not some organizations be more sensitive to the effects of hypnotics than others? I have known of individuals who had used sulphonal or trional, or both, nearly daily in 10 to 15-grain doses for two to three months without any marked evil results; while on the contrary I have seen others who developed toxic symptoms after using the same drugs and dosage for two to three weeks. I had opportunity to witness the toxic effects of trional in the case of a young man—a morphin habitué—who with suicidal intent took at one time 180 grains of trional. This young man had been excessive in every possible way. He had used cocain and morphin in large doses for months; he had drank one to two quarts of whisky daily for some time and had taken the "gold cure" three different times. His general condition can be imagined, yet such an overdose of trional gave rise to no critical symptoms. Four hours after the medicine had been

ingested he had the appearance of a man drunk from whisky. He was inarticulate in speech; inco-ordination was such that he could not walk at first and later would get about by stumbling and with some assistance. He could not feed himself and during the first twelve hours could not perfectly perform deglutition. Pupils were very dilated and non-responsive to light. There were coarse tremors in tongue and hands, pulse was rapid and weakened; temperature subnormal and respiration was shallow and never below twelve movements per minute. There was suppression of urine for eighteen hours, then a scanty flow of a dark cherry-colored urine with nothing out of the ordinary but a high specific gravity. The patient was given about the same treatment as if he had taken an overdose of morphin and at the end of thirty-six hours was in quite a natural condition aside from some muscular weakness and a slight deafness, which at first was very pronounced. I have observed that individuals habituated to the use of morphin or whisky are much less prone to be affected by the various hypnotics. I could cite many such cases where trional, sulphonal and hyoscin had been used in large doses and over prolonged periods yet produced but little hypnotic effect and as little apparent harmful results. One instance is where a man took 60 grains of trional, 30 of sulphonal, one-sixtieth of hyoscin and two drams of paraldehyde during a night, but slept none, while one-fourth of a grain of morphin gave him four hours good sleep. Another case is that of a young man—a paranoiac—who believed there was no medicine strong enough to injure him. He would take 40 grains of sulphonal and soon follow this with 30 grains of trional. This would give him a few hours sleep and be followed by a drowsiness during the succeeding day, but no evil effects were apparent, even though continued for several days.

Contrasted with the above cases are a few that show a sensitiveness to the effects of these hypnotics. A case in point was one of traumatic insanity in a man 45 years of age who was given sulphonal in 10-grain doses to relieve vague nervous symptoms and a mild delirium due to delusions of persecution. Under the influence of the drug he grew steadily worse and improvement was co-incident with its discontinuance, after which the patient cleared up in fourteen days. In this instance the patient was improving but was troubled with obstinate insomnia for which the sulphonal was given. The patient soon developed marked muscular weakness, difficulty of speech, anorexia and his delusions and hallucinations returned with renewed vigor. All these symptoms rapidly cleared up upon withdrawing the drug. A woman—paretic dementia—was discovered to have almost continuous diarrhea which failed to yield to any treatment. She complained of intense abdominal pain, was inarticulate in speech, had a rapid and weak pulse, subnormal temperature and such a degree of muscular weakness as to be unable to stand or get about at all. The urine was scanty, high colored and of high specific gravity. She slowly grew worse until a 10-grain sulphonal powder which she had been using daily for several weeks was stopped. Soon every disagreeable symptom disappeared.

Relative to the use of hyoscin hydrobromate, I wish to say that experience has taught me to use it very guardedly. In choosing a motor depressant we might much better use duboisin hydrochlorate. The latter drug has all the good and none of the bad properties of the former.

Hyoscin is nearly as drying to the fauces as atropin and in some cases aggravates the case very materially,

while I have never witnessed any such unfavorable results in using duboisin.

One case in evidence is that of a young woman suffering from hysterical insanity. In her case hallucinations of sight and hearing were scarcely evident until hyoscin was administered in one 1/100 grain doses every twelve to twenty-four hours. During three weeks this continued and all the time her hallucinations grew more painful until additional hypnotics were required. At the end of this time all drugs were discontinued. For four days her hallucinations were almost in abeyance but later returned but in a much milder form.

Again a patient with incipient organic brain disease had been given one-sixtieth grain of hyoscin every six hours for five days, during which time he was growing worse and showing hallucinations of hearing. Improvement in respect to the hallucinations was immediate upon discontinuing the hyoscin.

In still another instance a young woman suffering from incipient hallucinations of both sight and hearing grew rapidly worse and even delirious under the excessive use of hyoscin and trional. This same case began to clear up quite rapidly when these drugs were left off. I could continue with other cases demonstrating beyond a doubt that hyoscin, trional and sulphonal used injudiciously will in many cases greatly aggravate many of the symptoms in nervous and mental cases. This is especially noticeable in the intensification of hallucinations of hearing and increased excitability and muscular movements in cases of mania.

In considering the entire list of hypnotics we find but few that are reliable and none free from depressing and other undesirable effects. In every instance a hypnotic must be looked upon as a necessary evil and one to be dispensed with at the earliest possible moment. Many patients conceive the idea that "small doses" can do no harm and continue in their use indefinitely. Other patients become so dependent upon hypnotic drugs that they are alarmed at the thought of giving them up. I have found that many of these cases will begin to sleep naturally in a short time even though the drug is stopped, abruptly.

It is wise to resort to hydrotherapeutic and other natural measures and an occasional placebo is a helpful substitute. We are under the necessity of studying each individual case separately. One hypnotic will not be the best in every case. In paraldehyde we have a hypnotic speedy in its action, producing quite natural and refreshing sleep and accompanied by but few and slight after-effects. In fact its only disadvantage lies in its disagreeable odor and taste, and the odor left on the breath. It will be taken quite readily when mixed with coffee, aromatic elixir or made into an elixir according to the pharmacopeia. Trional is less prompt than paraldehyde but produces a more prolonged sleep, is best given in hot milk after retiring. It is often of advantage to give small doses of sulphonal during the latter part of the day and at bedtime 12 grains of trional. In doing this we usually secure for our patient six to eight hours good sleep. Sulphonal is very slow in producing sleep and very prolonged in its effects. It is best given in 5-grain doses two hours apart through the day until 20 and in exceptional cases until 30 grains have been taken. We can expect the patient to sleep that night and be drowsy the following day. In some cases depressing effects may be evident two and even four days after such dosage. Sulphonal is best used in cases of pronounced mental and motor excitement.

Chloral is a hypnotic of such long usage that everyone is familiar with its effects. It has been used much too little of late years and combined with the three bromids is often very serviceable.

Chloralamid is too unreliable to be found helpful, only in a few isolated cases. It seems desirable, in all cases where a hypnotic is necessary, to change frequently as less harm is thus done than where a patient is kept on the same one continuously, even though the new drug may produce fewer hours of sleep.

## Clinical Report.

### AN EMERGENCY CASE OF CESAREAN SECTION UNDER THE POSITIVE INDICATION, WITH TERMINATION IN RECOVERY.

MICHAEL T. NAUGHTON, M.A., M.D.

CHICAGO.

Mrs. X. was admitted to the Englewood Union Hospital on the night of July 25, 1901. She had been in labor for 24 hours. The following history was elicited: Bohemian, age 30; ii-para; 5 ft. 4 in. in height; weight 120 pounds. At the birth of the second child the cervix was severely lacerated and the perineum ruptured through the sphincter ani. For a period of six weeks she suffered from septicemia. Seven months after the birth of this child she entered a hospital and underwent an operation for the repair of the cervix and perineum. This was afterward shown to be an ablation of the cervix well into the lower uterine segment, and almost complete obliteration of the os uteri.

Diagnosis: An almost normal pelvis. The osseous system showed no signs of rachitis. There was no spinal curvature and the long bones were perfect in shape and conformation. A digital examination revealed a normal head presentation of a full-term child. The os uteri could not be demonstrated. The cervix was absent; its former site being occupied by an extensive mass of scar tissue which extended back to the fornix; the tissues imparted a rough parchment-like sensation to the touch.

Notwithstanding the fact that the pelvis was quite normal, the history of former deliveries showed that some cause rendered the birth of the child difficult, that forceps were employed and unusual force was used to extract the child and produce such extensive laceration as this case exhibited; that she had been in labor for twenty-four hours with absolutely no dilatation of the opening representing the os. This was found under anesthesia to be 1.8 in. in diameter, and was located in unyielding scar tissue from which amniotic fluid slowly exuded. Finally the severe uterine contractions, intensified by some ecobolic mixture, administered by a midwife, threatened to rupture the body of the uterus.

The question naturally presented was: Can this opening, surrounded as it is by pathologic tissue, be dilated sufficiently to allow the passage of the fetal head without producing an uncontrollable tear or hemorrhage? Or if that proposition is feasible, can a living child be born? We decided in the negative for the reason that it placed both lives in jeopardy: 1, in the mother's case, from fatal hemorrhage, due to a ruptured uterus; 2, the child's, from asphyxia. The patient was prepared for immediate laparotomy. There was no option as to a selected time for the operation. It had to be done at once. The woman was much exhausted, pulse 98, temperature normal.

Assisted by my associate, Dr. Arthur Werkmeister, an incision was made through the linea alba, above the umbilicus, two inches in length and rapidly enlarged to within an inch of the pubes, with strong scissors; no omentum or intestines presented between the uterus and abdominal wall. The uterus was forced from the abdominal cavity and covered with hot compresses, the abdominal wound being carefully covered with hot towels. I was unable to locate the site of the placenta from palpation or inspection before incision. The uterus was

opened by a vertical median incision in the fundus and enlarged to the extent of six inches with the scissors, through the fundus and anterior uterine wall. The thickness of the uterine wall was three-eighths of an inch. The placenta was adherent to the posterior wall, the membranes were torn through with the fingers and the fetus, which lay R. O. P., rapidly delivered by the feet. It did not breathe, but was soon restored by artificial respiration. The placenta was easily removed and the uterus contracted nicely, the walls increasing by this time to one and a quarter inches in thickness. Ergot was used after the evacuation of the uterine contents. Hemorrhage was slight after the contraction of the uterine musculature and was fully controlled by digital compression and hot sponges. Neither the elastic ligature nor a single hemostatic forceps, except the one used to clamp the cord, was employed in the operation.

Ten buried interrupted silk sutures were used to approximate the uterine muscle, followed by eight interrupted silkworm gut sutures, which included all the tissues down to the mucosæ. When the two rows of sutures were drawn tight the uterine wound was accurately closed and perfectly dry. The Lembert suture was impracticable on account of the tension due to active congestion of the organ.

The toilet of the peritoneum was brief, as no fluid had escaped into the abdominal cavity. The abdominal incision was closed by silkworm gut sutures.

The duration of the operation was thirty minutes. The uterine sutures were placed with unusual care, and that is the time-consuming step of the operation. There was scarcely any shock. She reacted nicely and her convalescence was uneventful. The prevailing temperature was 98.8; on the fourth day it reached 100 F., but subsided in a few hours. On the morning of this day she got out of bed and walked about the room. She repeated this endeavor on the tenth day, with no apparent ill effects, except a slight gastric disturbance. Her bowels were moved on the second day. The lochial discharge was odorless and ceased in two weeks. Lactation was not established. The only after-treatment she received was an occasional vaginal douche. The abdominal sutures were removed on the thirteenth day and the patient left the hospital "feeling fine," as she expressed it, three weeks from the time of entrance.

The child was a mature female, weighing seven and a half pounds, well formed and robust. It has done very well. Examination on December 12 revealed the uterus normal in size and limited motion; the parametrium was nearly free from infiltration; the sutures in the uterine wall could not be felt; the uterus was well up in the pelvic cavity, but could be made to descend with ease. There are probably some adhesions between the uterus and abdominal wall. The abdominal wound is firmly united.

#### REMARKS.

1. The continuous suture should not be used, as the involuting organ rapidly loosens it.
2. The buried suture possesses the advantage that after it is firmly tied the upper half of the wound can be thoroughly cleansed of blood, thereby giving ideal wound surface, with no interposing material.
3. Silkworm gut was used because silk occasionally acts as a syphon drain. If this occurred, one cavity would drain into the other.
4. The fetus should be rapidly delivered; otherwise the contracting uterus may grasp its head.
5. A satisfactory method of preventing fluids from entering the abdominal cavity will be found by having a rubber dam of such weight as is used by dentists, about one yard square, which should be kept ready for use in hospitals. Through a central circular opening from one and a half to three inches in diameter it can be slipped over the uterus and will effectually prevent fluids from entering the abdominal cavity.

The results obtained in this case answer in a measure the objections to the removal of a woman in this stage of labor, in an ambulance, over rough streets, or that the patient should be prepared the regulation time in advance in order to secure a favorable termination.

## MEETING OF THE AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS.

The second annual meeting of this association occurred in Cleveland, March 28 and 29. From the reports that have reached THE JOURNAL an interesting and valuable program was presented and the various sessions were well attended by representative teachers and investigators from different parts of the country. Among the papers the contents of which seem to be of especial interest to physicians in general or of more or less fundamental importance, the following may be mentioned: Dr. McFarland of Philadelphia presented a statistical study of the relation of tetanus to vaccination, in which it was brought out that the number of cases of tetanus after vaccination has increased to a relatively alarming extent during the last few years. The actual number of cases unearthed is still considerably below 100, but the greater part by far is of quite recent origin. From a consideration of all the facts the conclusion was reached that infection, as a rule, occurs through the vaccine, the principal reason for this conclusion being the occurrence of fifteen cases in a definite part of a large institution in Philadelphia, the inmates of which were vaccinated with a virus different from that employed previously. It is "up to" the manufacturers to surround the production of vaccine virus with all the precautions that ingenuity and knowledge can bring forth in order to rescue vaccination from this new though infrequent terror, sure to be exaggerated manifold by the credulous and foolish.

Dr. Warthin of Ann Arbor made an exceedingly interesting report with demonstrations upon the changes after splenectomy in sheep and goats. Since Warthin's recent work<sup>1</sup> on the hemolymph glands these peculiar structures have aroused much interest and it is evident that they are being actively studied in various places. Warthin's newer work shows that splenectomy in the animals mentioned is succeeded by great destruction of red blood corpuscles in which the retroperitoneal and other hemolymph glands play an essential rôle. Later, the existing hemolymph glands develop or change into large and pigmented lymph glands of the ordinary type, while new hemolymph glands spring up on the peripheral lymph nodes or independently in the fat, the first sign of their formation being a local dilatation of minute vessels. Apparently the bone marrow is the principal

seat of regeneration of red corpuscles. It was the structural details of this interesting and striking series of changes that Warthin presented, the exact mechanisms whereby they are accomplished being reserved for further study. On account of the great number of fundamental problems that are involved, these studies appear to be of great importance. Dr. Flexner, of the University of Pennsylvania, spoke on thrombi composed of agglutinated red corpuscles. He presented evidence that such thrombi may form in typhoid fever and other diseases in which agglutinating substances develop in the serum, thus reviving the old conception that certain hyalin thrombi are composed of red corpuscles. In connection with this it should be mentioned that Dr. Stewart of Cleveland, physiologist, made some interesting remarks upon the mode of action of certain hemolytic and agglutinating agents, which he divided into biologic and more purely chemie. These references will suffice to indicate that hemolysis and agglutination are coming to be of more and more importance in pathologic research.

A meeting of pathologists certainly would not be complete unless the subject of tumors came in for a good share of discussion. In the first place there were presented a number of valuable morphologic studies by Kelly, Ohlmacher, Larkin and others. Dr. Le Count's forcible presentation of the analogies between the so-called Plimmer's bodies, which many regard as the parasite of carcinoma, and the centrosome and other structures normally found in the archiplasm of many cells, made a decided impression. It seems that the cancer parasite enthusiasts have neglected greatly if not wholly the very important fact that before certain intracellular bodies are regarded as parasites it must be shown that it does not concern normal or abnormal centrosomes and other formations of that kind. Nichols, from Boston, reported upon the lesions produced by the blastomycetes of Plimmer and San Felice, showing that they were wholly granulomatous in character. Leo Loeb reported further upon the transplantation of tumors in animals (rat), an important fact brought out being that the power of inducing tumor growth persists in pieces kept outside the body for five days.

Mere mention of the reports of His, Libman, Charlton and Park on bacteriologic studies of various kinds will indicate that this field was well represented also. In the evening of the last day of the meeting, the Cleveland Medical Society was addressed by Councilman, who spoke on the "Pathology of Smallpox," basing his remarks on the results of some 50 autopsies made during the recent epidemic in Boston. The most noteworthy findings in this series were the remarkable reduction of polymorphonuclear leucocytes in smallpox, the constancy and severity of the secondary streptococcus invasion, and the necrosis in the testicles and bone marrow. A splendid exhibit of gross smallpox lesions was made to the pathologists by Magrath and Brinckerhoff of Bos-

1. THE JOURNAL A. M. A., May 25, 1901.

ton. This study of smallpox bids fair to equal the earlier Boston studies in the pathology of the acute exanthematous diseases.

On the whole it is evident that this meeting is a good indication that research in pathology and bacteriology is progressing favorably among us; that it is to a considerable extent experimental; and that highly creditable work of permanent value is being produced.

#### SCARLATINAL NEPHRITIS.

Scarlet fever is one of the most dreaded of all the infectious diseases. It has been estimated that it causes one-twenty-fifth to one-twentieth of the entire mortality in England and America. Since we are unable to prevent the disease, our efforts must be directed toward avoiding the unfavorable attendants of the fever and convalescence and in modifying them in a favorable manner when they occur.

Of all the complications and sequelæ of scarlatina, the most important is the affection of the kidneys. Adolf Baginsky, who is well known as a skilful clinical observer of wide experience, has recently presented the subject of scarlatinal nephritis<sup>1</sup> in a masterful manner. His article is founded upon 88 cases occurring in 919 cases of scarlatina observed in hospital during 5 years. In the cases studied the onset of the nephritis occurred from the 6th to the 30th day. In a large proportion of cases the nephritis was accompanied by fever which sometimes rose gradually for two or three days before the nephritis could be demonstrated. As a rule, with the occurrence of nephritis, the quantity of urine became less, but cases were not so uncommon in which there was no effect upon the quantity of urine and the specific gravity remained unaltered. In still other cases a considerable increase in the secretion of urine accompanied the nephritis. Many cases which showed but moderate albuminuria developed uremic symptoms, while others in which the amount of albumin was large terminated favorably. In general, cases with prolonged and marked albuminuria were apt to be severe and prolonged. Out of 37 cases which entered the hospital within the first five days after the beginning of the scarlatina, only a single one exhibited a marked development of uremia. Of the cases coming to the hospital later than the fifth day, a large proportion had general dropsy on admission. Among the cases coming to the hospital early, many severe and even fatal cases were included, so that the failure of dropsy to develop in any of them can only be explained as being due to the hospital treatment. In two fatal cases, anuria without uremic symptoms was observed.

The prognosis in scarlatinal nephritis must be very guarded. Of 88 cases, 11 died—12.5 per cent. Chronic nephritis followed in five cases and possibly in others which could not be kept under observation for a sufficient length of time to certainly exclude it. Out of 38

cases of chronic nephritis in children observed in the hospital, 9 could be traced to previous attacks of scarlet fever.

Baginsky considers scarlatina a most important factor in the production of chronic nephritis, which may follow directly upon the acute attack or may develop after an intercurrent free period. He urges the necessity of watching the condition of the kidneys for some time after scarlatina, especially after acute scarlatinal nephritis. The idea seems to be generally prevalent that post-scarlatinal nephritis is not liable to be followed by chronic Bright's disease. Rotch says that it is rare for renal disease following scarlet fever to become chronic. Holt was formerly of the same opinion, but larger experience has convinced him that it is not very uncommon for chronic nephritis to follow the acute and it may make its appearance even after an interval of years.

These observations direct attention to the necessity of watching the kidneys of such patients for a considerable length of time.

The routine treatment of scarlatina in Baginsky's hospital is hydrotherapy, quiet in bed even for the lightest cases, and milk diet. This does not prevent the occurrence of nephritis, but reduces the mortality to the minimum. Since 1896, a rigid milk diet has been carried out in the hospital in all cases, with the result that general dropsy has not developed in any case treated in the hospital from the start, and severe uremic intoxication has been almost entirely absent. Even in severe cases of scarlatina, so severe general symptoms of nephritis have not been observed as in cases coming from the outside later in the disease. Under this treatment only one case of nephritis has developed which proved fatal and it was complicated by phlegmonous angina. For three weeks the diet is practically only milk. Substances rich in nitrogen are strictly excluded, especially bouillon and meat extracts. In the fourth week some vegetables are allowed and at the beginning of the fifth week, when no complications are present, the patient is allowed to sit up. Only at the beginning of the sixth week are bouillon, eggs and light meat added to the diet. Milk has now come to be generally considered the best diet for scarlatina patients, and its use for at least four weeks is urged by such clinicians as Rotch and Holt. Rotch thinks such feeding may perhaps ward off a certain number of cases of nephritis.

#### NERVOUS JAUNDICE.

In not a few cases, the diagnosis catarrhal jaundice, though seemingly forced upon the practitioner by the absence of any other condition to account for the absorption of bile, is eminently unsatisfactory. Not infrequently there have been no symptoms of a preceding catarrhal process in the intestines and no preliminary disturbance of gastro-intestinal digestion. In recent years French clinicians particularly have called atten-

1. *Archiv für Kinderheilkunde*, xxxiii, 1902.

tion to the not uncommon occurrence of jaundice after severe emotional strains—the *icterus ex emotione* of the older medical writers. It is a well-recognized fact that in women particularly an emotional storm may be followed by slight jaundice. Neurotic individuals are prone to have slight amounts of icterus noticeable, especially in the conjunctiva, that are sometimes set down to blood hemolysis, under nervous strain. It would be more satisfactorily explained as due to nervous disturbance of the biliary mechanism which, as we shall see, is dependent on a group of the most complicated co-ordinate reflexes in the system.

Curiously enough, this form of nervous jaundice, apt to be considered a recent observation, embodies a very old idea in medical history, and references to it, even in non-medical writers, are not uncommon. Shakespeare said in "The Merchant of Venice" (act 1, scene 1):

And let my liver rather heat with wine  
Than my heart cool with mortifying groans.  
Why should a man whose blood is warm within,  
Sit like his grandsire cut in alabaster?  
Sleep when he wakes and creep into the jaundice  
By being peevish.

In fact this is the only sense in which Shakespeare uses the term jaundice. The word occurs but once more in all his plays and then in "Troilus and Cressida" (act 1, scene 3) in the passage:

"What grief hath set the jaundice on your cheeks?"

At the meeting of the New York Academy of Medicine, Feb. 6, 1902, Dr. S. J. Meltzer pointed out in a paper on the influence of inhibition, how complex is the nervous mechanism of the biliary system and how easy it is disarranged. The presence of food in the duodenum causes a reflex opening of the ampulla of Vater, through which the biliary and pancreatic secretions are evacuated into the intestine. This reflex does not suffice, however, to bring the bile to the intestine, for there must be besides an active contraction of the gall-bladder and a stimulation of the secretory function of the liver cells. The splanchnic fibers of the vagus distributed to the intestinal walls are known to provide the inhibitory nerve supply to the muscles of Vater's papilla. The vagus has an inhibitory set of fibers for practically all organs to which it is supplied. In neurotic patients especially, the inhibitory functions are prone to be manifest, because of the irritative condition of all nerves. It is usually in such individuals that disturbances of heart rhythm from inhibitory effects become most noticeable.

It would not be surprising, then, if inhibitory nervous jaundice, due to failure of the ampulla of Vater to open at the proper time, should occur more frequently than is at present supposed. Where previous irritative conditions of the intestine have been noted, this may account for as many cases of so-called catarrhal jaundice as are attributed to the actual spread of a presumed catarrhal inflammatory process from the intestine into the biliary ducts. It is not improbable that the cases

of jaundice accompanied by slight biliary colic in which the condition is relieved after a time, without the appearance of a gallstone in the stools, may belong in this category of ailments. Even in cases where the manipulation suggested by Gerhardt is successful and massage over the fundus of the gall-bladder relieves the stasis in the biliary tract, it may still be true that nervous and not catarrhal jaundice is present. The massage may overcome the inhibitory closure of the mouth of the ampulla and the bile ducts may remain open when once the obstruction is relieved. It would seem, then, that in many cases now classed as catarrhal jaundice and treated as such, treatment for the general nervous condition is indicated, especially the use of antispasmodic remedies to relax the reflex spasm set up by irritation of the intestines. The use of purgatives, now so commonly recommended, would in these cases be especially contra-indicated. The ideas involved in this claim for the existence of a purely nervous jaundice seem to be of a practical character that commends them to further study and careful application in select cases.

#### THE THERAPEUTIC VALUE OF ALCOHOL.

The long existence of a common belief is by no means infallible evidence of its correctness. It is proverbial that superstition dies hard, and the judicial attitude is far from universal. The scientific physician, however, must ever view his facts dispassionately and base an unprejudiced opinion upon the fullest measure of knowledge at his command. Alcohol has so long been employed both as a beverage and as a therapeutic agent that its usefulness has come to be taken for granted and the statement as to its efficacy seems to have been handed down from generation to generation without serious question. There has, however, now accumulated a sufficient mass of evidence of reliable character to permit of intelligent discussion of the entire subject. Directly contradictory opinions are held by different authorities as to the value of alcohol as a stimulant to the circulatory, the nervous and the digestive system, as a food and as a general remedial agent in the presence of various morbid states.

According to the opinion of Dr. H. F. Hewes,<sup>1</sup> expressed in the course of an admirable symposium on the value of alcohol as a therapeutic agent, held a short time ago by the Suffolk District Medical Society, alcohol is to be considered pharmacologically as a narcotic or an anesthetic, being most closely allied in action to ether, chloroform and chloral. In the sense of causing disturbance of bodily function it must be looked upon as a poison. It acts as a local irritant to the mucous membrane of the mouth and the stomach, inducing hyperemia and reflex excitation, and after absorption also direct excitation, of the nerve-centers. It is largely oxidized in the body and it has a destructive effect upon the protoplasm of the tissue-cells. The preponderance of evi-

<sup>1</sup> Boston Med. and Surg. Jour., March 13, 1902. THE JOURNAL A. M. A., March 29, 1902, p. 841 and 842.

dence tends to show that alcohol does not act as a cardiac stimulant, except for its initial irritant effect, so that its use for this purpose, especially if long continued, is irrational. It is rather a depressant to the heart and circulatory mechanism, as it is also to the nervous system. Taken with food it may serve digestion by stimulating appetite through its pleasant taste and its slight irritant effects. Although it acts as a tissue-sparing substance or food this effect is more than counterbalanced by its destructive or poisonous influence upon protoplasm. Its use as a food is rational, therefore, only when ordinary food-substances can not, and alcohol can be, utilized. Finally, definite scientific evidence is yet wanting to show that alcohol has any special therapeutic activity in the presence of certain definite morbid conditions, such as the various forms of infection.

Dr. F. C. Shattuck, in the same symposium, expressed the belief that while a healthy man under ordinary circumstances in a temperate climate does not require alcohol he may use it moderately and habitually—especially if diluted and taken but once in 24 hours, preferably with food—for years without apparent harm; and also that alcohol is the most trustworthy remedy to counteract the toxemic phenomena attending various infectious processes. Dr. E. N. Whittier expressed his conviction of the great therapeutic value of alcohol as based upon personal and professional experience in extreme degrees of disease.

Dr. E. G. Cutler pointed out that alcohol is no longer used as a ration in the army or the navy or by explorers in arctic or tropical regions. Also it has been discarded—except in the smallest amounts in weak solution—in the preparation of athletes for contests. As to its value in relation to acute infectious diseases it seems rather to predispose to than afford protection from these, while its antipyretic effects, and its usefulness as a food, as a stomachic and as an analeptic or stimulant to the circulation are inconsiderable, if not more than offset by its deleterious effects. Even in the case of chronic infectious diseases, of cardiac, gastric and intestinal diseases, its slight useful effects are but temporary and of brief duration.

As an evidence of the decline in the use of alcohol in the Massachusetts General Hospital, Dr. R. C. Cabot pointed out that the average cost annually for this medicament for each patient in that institution had fallen from \$1.48 in 1884 to 29 cents in 1900. Dr. E. P. Joslin spoke of the value of alcohol in the treatment of diabetes in replacing a certain amount of fat in the body, in enabling the patient to take more fat, in lessening the sense of hunger, in inducing a sedative effect. Not more than 5 ounces should be taken in the twenty-four hours with these objects in view, while from half an ounce to an ounce will usually be sufficient. The amount required will be proportionate to the severity of the case. Alcohol is valuable also in antagonizing the acid intoxication upon which diabetic coma is believed to depend.

It will thus be seen that the drift of sentiment as to the value of alcohol is to the belief that this agent is not necessary and may be a source of harm in conditions of health, and that it has little or no value as a therapeutic agent in the presence of disease.

#### COMMERCIALISM IN MEDICAL EDUCATION.

We are apt to congratulate ourselves on the advantages afforded by medical progress, the facilities of study and investigation and the generally better standpoint of the physician of to-day over the one of the past. This is only one point of view: there is another that is by no means so pleasant a one to take of conditions as they exist. The doctor of to-day seeking fields of practice, after a much greater outlay of time and money than his predecessor of even a few years back, finds himself confronted with conditions that are yearly becoming harder in an overcrowded profession and a gradually ever-narrowing field of work. His diploma is no longer a valid credential: it may admit him to an examination provided it meets the requirements, but in only a limited and ever-narrowing section of our country is it alone sufficient as was formerly the case. Under present conditions, moreover, should he wish at any time to make a new start in another part of the country he must go through the same or similar tests with the disadvantages of lack of the freshness of memory in all the branches that he possessed at his graduation. Altogether, he works more and pays more for a lessened chance of success. This, however, is a necessary evil in the present conditions of medicine and while it is to the disadvantage of the individual at times it is of benefit to the profession as a whole and is in the inevitable order of progress. When interstate reciprocity, or, what is more practical, and infinitely better, a national examining board, is secured, the valid objections will be practically nil. A much more serious matter is the overcrowding of the profession and the multiplication of medical colleges.

A recent article by Dr. Emil Amberg<sup>1</sup> forcibly calls attention to these evils and the other disadvantages which the neophyte in medical practice has to meet. It is especially, however, the masked commercialism in this multiplication of medical colleges that he exposes. We are proud to consider our profession as one, more than any other, altruistic in its motives and yet we belie this claim daily by the existence of uncalled-for doctor factories, the real reason for the existence of which is the desire to advertise and financially aid the members of their faculties. The ones to which we refer are mere corporations for profit, existing, it may be, under false pretenses, even if they do not turn in financial dividends directly to their stockholders. Whether Dr. Amberg's remedy to have only state institutions is the only one, may be disputed by some and difficult to apply, but there is no doubt that a rigorous state supervision and legislation toward their limitation

1. Philadelphia Med. Jour., March 22.

would be most desirable. As it is the conditions are, as he says, unhealthy, and his charge that a medical oligarchy exists for its own profit and tyrannizes over the profession, can not be said to be without foundation, but comes too near to being a practical hard fact, and the sooner this is generally realized, the better.

We are aware that this sounds harsh when it is appreciated that very many of the most respected members of our profession fill the chairs in those superfluous medical colleges, but perhaps the harsher it seems the better. If we could only get the best men to refuse positions in any but a few of the best-equipped and well-known institutions and then make the position seek the man, not the man the position, half the work would be done. The reform will not be effective by easily passed resolutions, but only by earnest self-denying work. There are already some signs of a movement in this direction, in Ohio, for example, but it is only the merest beginning of what needs to be done. It is a matter that urgently needs the attention of State Boards, the Medical College Associations and the House of Delegates of the American Medical Association.

#### ANIMAL EXPERIMENTATION AND THE ANTI-VIVISECTIONISTS.

A service to mankind, if not indeed to the brute creation also, has been rendered in the issuance in book form<sup>1</sup> of the statements made by the remonstrants to the proposed Massachusetts legislation against physiological experimentation on animals. The force of these statements, coming from leading clergymen and teachers as well as from physiologists and physicians, is shown in the fact that the legislative committee to which the proposed act was committed unanimously reported "leave to withdraw," thus squelching for the time the antivivisectionist movement. If anyone requires a convincing series of arguments against the special phase of zoophile fanaticism here exposed, and undoubtedly there will be such occasions, he will find in this little volume a most valuable means of reference. The opening argument by Dr. Bowditch and the closing one by Dr. Ernst are alone sufficient to show up the case, but here they are reinforced by other most convincing statements. The inconsistency of the antivivisectionists is thoroughly exposed by men whose testimony no one with any regard to his own reputation would care to impeach, and the truth that a morbid satisfaction with one's own virtuousness is often the cause of very unethical conduct has seldom been made more manifest. Dr. Bowditch shows how the opinions of the late Dr. Bigelow were misrepresented by the advocates of the bill, who seem to even have suppressed a letter sent by him to one of their publications. Dr. Ernst also furnishes similar evidence both as to Dr. Bigelow and Huxley, the latter of whom was also misrepresented by the zoophiles as favoring their cause. It is not surprising that the legislature made short work with the measure, especially after its committee had further satisfied themselves by personal inspection of various laboratories in the state. With these and Dr. Keen's letters,

published in *THE JOURNAL*, there hardly seems any need of further argument on the subject. Nevertheless, it is safe to prophesy that the sentimental antivivisection agitation will be periodically revived; it is almost as perennial as truth, though it has hardly anything else in common with it. Hence, it is well that we have so effective an arsenal of argument against it, as is here furnished, for use with legislators and others who may be in danger of being misled. We would be glad to see this work obtain the widest circulation with the general public, and bespeak for it the efforts to that end of our profession.

#### POLITICS AND PUBLIC HEALTH IN SAN FRANCISCO.

The new mayor of San Francisco has given evidence of what sort of man he is by the removal of the four remaining members of the old city board of health. The reasons for this as given by him are much the same as those influencing Governor Gage in his remodeling of the state board of health and his crusade against Dr. Kinyoun and his associates. Mayor Schmitz says that he has for three months "carefully examined and investigated all accessible reports and records" and has personally inquired into numerous specific cases declared by the board to have been bubonic plague and is unalterably convinced that "bubonic plague has not existed and does not exist in San Francisco." The medical profession of the country and of the world, only excepting a few commercially-influenced physicians in San Francisco and California, is convinced that bubonic plague has existed in that city and state and is very far from being satisfied that it does not still exist there to some extent and that it is not liable to break out into an epidemic at any time. There has been a certain degree of security felt because it was believed that there existed, in San Francisco at least, an honest board of health that would do what it could to protect the city and country from such a calamity. The removed members have, as we believe it was their duty to do, sued out an injunction against the mayor's act and, therefore, are still in office. It is to be hoped this injunction will stand; if it should not, the possibilities of quarantine against San Francisco to its commercial disadvantages are certainly not decreased. The dreaded possibility is that a pliable board of the mayor's creatures will suppress facts of actual cases and neglect the requisite precautions. The only hope will be that there may be some among them whose conscience is held above the influence of commercialism, but it is hard to see how this can be, or how any conscientious or self-respecting physician can accept the appointment, given, as it clearly is, with the understanding that no cases of plague are to be recognized. It is a certainty that under the circumstances the mayor's appointees will not command the confidence of the profession abroad. The situation is an unpleasant one and its possible consequences are still less satisfactory to contemplate.

**Potassium Permanganate in Dysentery.**—Kusmizki reports excellent results in twelve cases of dysentery treated with 30 gm. of castor oil every day, and twice a day a rectal injection of 800 gm. of a tepid 1 per 4000 solution of potassium permanganate.—*Vocmo-Med. Journal*, November, 1901.

1. "Animal Experimentation," Little, Brown & Co., Boston, 1902.

## Medical News.

### CALIFORNIA.

**Berkeley Health Board.**—The trustees of Berkeley have appointed the first board of health that the town has ever had as an independent body. It consists of Dr. Frank H. Payne, present health officer, and four other physicians of various schools.

**Fakirs in Trouble.**—The police of Los Angeles have commenced a crusade against the many imposters who are robbing the people of that city under the pretense of giving them medical treatment. "Dr." G. Yglesias, who was in similar trouble a year ago, was one of the first to be arrested.

**Mayor Removes Health Board.**—Mayor Schuntz has removed Drs. John M. Williamson, Rudolph W. Baum, Vincent P. Buckley and W. B. Lewitt, members of the San Francisco Board of Health, and has appointed in their stead Drs. J. Coplin-Stinson, Albert S. Adler, Tullio A. Rothanzi and Miles E. Van Meter. Dr. Coplin-Stinson has been elected temporary president of the board. On March 26 Judge Cook issued an order restraining the newly-appointed board from interfering with their deposed predecessors.

### ILLINOIS.

**Globe Hospital, Freeport.**—The former residence of ex-Congressman Burchard, remodeled at an expense of \$9000, is to be used as a hospital. It will be ready to receive patients May 1.

**Sanatorium Burned.**—The Carlsbad Hotel and Sanatorium at Nashville was burned, March 23. The loss is \$15,000, with \$10,000 insurance. The institution was under the management of Dr. Harrison F. Fitzgerald of St. Louis.

**City Physician Acquitted.**—In the case of Dr. Le Roy P. Barstow, city physician of Quincy, charged with failure to report a case of contagious disease, as the evidence showed that he had reported it to Theodore Featheringill, overseer of the poor, and he in turn reported it to Dr. Wellenreiter, the court held that Dr. Wellenreiter was an agent of the secretary of the board of health and discharged the defendant.

### Chicago.

**Rush College Commencement.**—The quarterly commencement exercises of Rush Medical College were held April 4. Professor Senn delivered an address commemorative of the life work of Prof. Christian Fenger.

**Exhibit Disappears.**—The exhibit of the Health Department, which was awarded the gold medal at the Pan-American Exposition, has disappeared, and the solace of having been awarded the medal is all that remains to the department.

**Fraternity Men Meet.**—The Phi Rho Sigma Fraternity of Chicago, consisting of professors and students of the various medical colleges of the city, held its annual interchapter, March 15. Dr. George F. Butler of Alma, Mich., officiated as toastmaster.

**Clinic by Dr. Vaughan.**—Dr. Arthur R. Edwards, secretary of the Northwestern Medical School, announces that Dr. Victor C. Vaughan, dean of the medical department of the University of Michigan, will give a medical clinic in the laboratory building, 2431 Dearborn St., at 11 a. m., April 9, to which physicians are cordially invited.

**Dr. Wing to Leave Chicago.**—Dr. Elbert Wing announces that he discontinues the practice of medicine in Chicago, April 1, and will resume it about October in Los Angeles, Cal. He was given a farewell dinner by Dr. Thomas L. Gilmer, March 28, at which Drs. Frank Billings, E. C. Dudley, H. B. Favill, L. L. McArthur, Frank Cary, E. Wyllys Andrews, Frank T. Andrews, Robert Harvey, Junius C. Hoag, T. J. Watkins, Edward Capps, and Clement L. Clapp were present.

**Medical Headquarters Plan.**—The Physicians' Club discussed at its meeting, March 31, the project to build a home in the business portion of the city which should serve as a medical headquarters and general meeting-place for medical men, with accommodations for the various branches of the Chicago Medical Society. As a preliminary step, the club appointed a committee of five—Drs. Nicholas Senn, Edmund J. Doering, Joseph Zeisler, David W. Graham and Harold S. Moyer—to confer with the trustees of the Chicago Medical Society and arrange plans whereby the fund may be increased.

**Warning Against Epidemic Diseases of Childhood.**—The almost epidemic prevalence of the communicable diseases of childhood has caused the Commissioner of Health to renew his

efforts to secure the co-operation of the public school teachers in preventing their spread. Through the assistance of School Superintendent E. G. Cooley a copy of the circular, "Suggestions for the Teaching of Cleanliness Among School Children," is being put in the hands of every teacher, with the request from the superintendent that they be continuously enforced. The gist of these suggestions is that much may be done to restrict the spread of contagion by teaching habits of cleanliness.

**Officer of the Day.**—Beginning April 1, the County Hospital has a "medical officer of the day," whose duties are thus defined by Warden Healy: "On and after April 1, 1902, the twelve senior internes of the Cook County Hospital—namely, eight from the regular school, two from the homeopathic school and two from the eclectic school—shall in rotation perform the duties of 'medical officer of the day.' Such service will require the officer of the day to visit each ward and operating room and familiarize himself with every detail pertaining to all medical and surgical requirements and note any neglect of duty by attending physicians, surgeons, members of the house staff, nurses and others and to hear any complaints from patients. He shall make a full and complete report daily in writing of his visits and of conditions as he may find them during his service as such officer."

### KANSAS.

**Alumni Banquet.**—The alumni of the College of Physicians and Surgeons, Kansas City, Kan., gave a banquet to the graduating class of the college, March 25.

**Alleged Abortinist Acquitted.**—Dr. Robert E. Gray, Garden City, who has been on trial for causing the death of a young girl by an unlawful operation, was acquitted, March 26.

**Kansas Medical College.**—The thirteenth annual commencement exercises of this college were held at Topeka, March 20. A class of sixteen was graduated. Dr. John E. Minney, dean of the college, acted as master of ceremonies. The general address was delivered by Rev. Daniel M. Fisk, D.D.; Dr. Josiah P. Lewis made the faculty address and Dr. John C. McClintock, president of the board of trustees, conferred the degrees.

### KENTUCKY.

**Seventy-Five Per Cent. Indicted.**—It is announced in a Louisville paper that six indictments have been found against three physicians of Mount Olivet, for giving prescriptions unlawfully. According to the latest directory, this town boasts only four physicians.

**Commencement.**—On March 28 a class of 31 was graduated from the medical department of the University of Louisville. —Louisville Medical College graduated a class of 29, March 26. Dr. A. M. Cartledge presided and the salutatory was delivered by Dr. S. T. Taylor.

**To Report Contagious Diseases.**—The Owensboro Board of Health has promulgated an order requiring physicians and others having the care of persons with any contagious or infectious disease to report the fact to the board within twenty-four hours under the penalties of the law.

### MARYLAND.

**Bequest to Home for Incurables.**—The late Mrs. Rebecca C. Spence, Baltimore, left a bequest of \$3000 to the Home for Incurables.

**The Week's Deaths.**—The deaths in Baltimore for the week ended March 29 were 192, 24 being from pneumonia, 19 from consumption, 2 each from diphtheria and typhoid fever.

**Anti-Expectoration Detective.**—The Health Department of Baltimore has detailed a detective to ride in the street cars and warn spitters of the ordinance against expectoration. Later, arrests will be made.

**Personal.**—Dr. Campbell Fair Plautt has been appointed Health Warden, vice Dr. W. A. Davis, resigned.—Dr. Ira Rensen qualified as a member of the School Board, taking the place of Dr. Daniel C. Gilman, resigned.

**Suit for Chloroform Death.**—Drs. Charles J. Keller and Morris C. Robins, Baltimore, were jointly sued in the Court of Common Pleas for the death of an infant 9 months old. It is alleged that the child's death was caused by the wrongful and unskilful use of chloroform in a surgical operation without the knowledge or consent of his parents.

**Recent Legislation.**—The Medical Practitioners' Bill has passed both houses of the legislature, and now awaits the Governor's signature. This requires, among other things, a four-year college course. The Omnibus Bill, with appropriations

for the various hospitals, etc., has passed. The Infectious Disease Hospital has been killed in the legislature.

**New Public Bath Opened.**—On April 1 the representatives of Mr. Henry Walters handed to the mayor of Baltimore the deed and keys of the new public bathhouse on Columbia Avenue. The cost has been \$27,000. The building is 40 by 70 feet, with terraced front. The architecture is the free colonial. The first bath was erected by Mr. Walters 18 months ago, and with his present gift represents an expenditure of \$52,000.

**The Lunacy Commission.**—According to the seventeenth annual report of the Lunacy Commission of Maryland there were on November 30 last in the hospitals, asylums and almshouses of the state 2672 insane, an increase over the previous year of 145. Of these, 407 were colored. The president of the commission urges the increase of salary for the secretary, whose duties require two annual visits to each county, frequent attendance at court, and demands without number on his time and labor. The secretary asks for the appointment of a permanent assistant secretary.

#### MICHIGAN.

**Measles in Kalamazoo.**—The report comes that the ward schools of Kalamazoo are full of measles. There are 135 cases, 39 of which were reported last week.

**Hospital for Blind School.**—The new hospital building at the State School for the Blind, Lansing, which has been erected at a cost of about \$8000, has been accepted by the board of control.

**Fees from Licenses.**—The State Board of Registration in Medicine reports a cash balance on hand, March 1, of \$1,733.31, which has been derived from fees received from physicians' licenses.

**Summer Session at Ann Arbor.**—The summer session for 1902 of the medical department of the University of Michigan will extend from June 23 to August 8. The courses offered are classified as special, designed for graduates and advanced students, for which no credit will be given and credit courses, which duplicate certain portions of the regular curriculum, and on the satisfactory completion of which, credit will be given. No allowance for time will, however, be given for work done in the summer school. Courses are announced in thirteen different subjects.

#### NEW YORK.

**State Charities Bill.**—Governor Odell has signed the state charities bill, which provides for a fiscal governor to be appointed by the governor at a salary of \$6000 a year to supervise expenditures by state charitable institutions, and for a state board composed of the governor, the state comptroller and the president of the State Board of Charities, to pass on all plans for additions and improvements to the institutions.

**The antitoxin laboratory** of the State Department of Health, which was inaugurated in 1901, is located in the Bender Laboratory, Albany, while the animal house is located several blocks away, with a capacity of 15 large animals. The state has already made an appropriation of \$20,000. The object of the laboratory is to manufacture under state control the various antitoxins for use in all state institutions and for the indigent poor. Diphtheria and tetanus antitoxin are now ready for use. It is hoped that effective antitoxins for tuberculosis, typhoid fever and various other infectious diseases may be obtained by original research. The laboratory is under the direction of Dr. Herbert D. Pease.

#### New York City.

**Hospital Saturday and Sunday Collection.**—The collection amounted this year to \$66,000, which is to be distributed among hospitals in this city.

**Municipal Consumption Hospital.**—Four buildings are to be added to this hospital and the appropriation for its support has been increased by \$48,000 a year.

**Cumberland Hospital Staff.**—At a meeting of the staff of Cumberland Street Hospital, Brooklyn, March 21, Dr. William H. Pierson was elected vice-president and Dr. Orlando S. Ritch, secretary. The hospital will open about May 15.

**City Hospitals Fire Traps.**—An inspection of the city hospitals has brought to light the fact that Bellevue, Fordham and Harlem Hospitals are veritable fire traps, and that Gouverneur Hospital alone comes up to the standard required by law.

**Microscopes Stolen from Willard Parker Hospital.**—For some weeks past there have been mysterious disappearances of microscopes and lenses from the bacteriologic department of the

Willard Parker Hospital. Detectives have been working on the case, and have at last arrested an employee of the hospital, and two other persons, one an optician, who are suspected to be accomplices. In the optician's place were found some of the stolen goods, worth about \$1000, but the total value of the stolen property is estimated at \$4000.

**The Ward Damage Suit Against St. Vincent's Hospital.**—This now notorious suit of Miss Helen D. Ward against St. Vincent's Hospital, for damages because of burns received by the careless use of hot water bottles, has now passed its fourth trial. The plaintiff was awarded \$18,000 damages, \$1420 for medical services made necessary by reason of the injuries received in the hospital and five per cent. for her legal counsel. On the first trial the complaint was dismissed; on the second the jury disagreed, and on the third \$10,000 damages was awarded.

**Shameful Treatment of Paupers.**—The new city administration is demanding larger appropriations in order that the paupers may receive decent care. Incidentally, it has been made known that the 2500 inmates of the almshouse last year were fed at a per capita cost of about ten cents a day. The commissioner declares that for a year these persons lived on bread and coffee for breakfast, bread and stew for dinner and bread and tea for supper, without sugar, butter or vegetables. The commissioner very properly says that while he is not anxious to make the fare especially attractive, he thinks such miserable diet calls for a change.

**College Education Demanded for Physicians.**—The chief undergraduate paper of Columbia University, the *Columbia Literary Monthly*, has stirred up a hornet's nest by declaring "that the greater part of the students at our medical school—the College of Physicians and Surgeons—are not only uncultured, but often even uncouth, thus being fundamentally unfit to become the highest type of their profession. A degree as the entrance requirement would go far to remedy this state. Unfortunately, many worthy men would thus be barred out, but the good resulting from such an injustice would far outweigh the injustice itself, and the benefit to the institution would be vast, although its number of students might be greatly diminished." The way the present state of affairs works to the detriment of the students generally, is well stated in the following extract from another part of the same editorial: "At the College of Physicians and Surgeons those who have made the correct start are retarded by those who have not, while the latter are at a disadvantage when compared to their fellows. This tends to want of balance."

#### Buffalo.

**The new consumptive pavilion** at the Erie County Hospital has been opened for the reception of patients.

**Money for Gratwick Laboratory.**—The annual supply bill contains an appropriation of \$15,000 for the Gratwick laboratory for the continuance of the cancer investigations.

**Mortality.**—The monthly report of the Department of Health for February shows a death-rate of 12.90 per 1000 per annum. The total number of deaths was 379 as compared with 394 for the corresponding month of 1901.

**Personal.**—Dr. Dewitt Sherman has returned from Atlantic City.—Dr. Julius Ullman has returned from New York and Atlantic City.—Dr. Edward J. Meyer is seriously ill in Florida.—Dr. Harvey R. Gaylord, wife and child sail for Europe shortly.

**County Sued by Pasteur Institute.**—The County of Erie has been sued by the Pasteur Institute of New York to collect a bill for \$4600 for the treatment of Erie County hydrophobia patients. The county officials take the position that the bill should be paid by the state.

**Interne at Jail.**—To insure the more humane treatment of sick prisoners at the jail the Board of Supervisors has authorized Dr. Frank Bruso, the jail physician, to appoint a resident third-year student interne, who shall receive his board, laundry and lodging at the expense of the county.

**The New Marine-Hospital.**—It is understood to be the intention of the secretary of the treasury to have the work of construction of the new marine-hospital at Buffalo, the appropriation of \$125,000 for which was recently secured, begun next fall. The hospital will accommodate 100 patients. The site has as yet not been selected.

#### OHIO.

**Ohio State Pediatric Society.**—The annual meeting of the Ohio State Pediatric Society will be held at Toledo, May 27 and 28.

**Hospitals.**—During 1901 St. Elizabeth's Hospital, Cincinnati, treated 1856 patients, of whom 713 were women. There were 70 cases of alcoholism and 84 of tuberculosis. —Ashtabula General Hospital has been incorporated with a capital stock of \$10,000.

**Physicians Mulcted.**—In a Columbus court, March 20, Mrs. Beebe Cuthrell obtained a verdict of \$1000 in a suit for \$20,000 brought against Drs. Will J. Means and J. Willehour Barnes, who she claimed had performed an operation on her at the Protestant Hospital of a different nature from one she had authorized. The defendants at once filed a motion for a new trial.

**New Surgical Building for Women.**—The new surgical department for women of St. Vincent's hospital, Cleveland, was opened, March 19. The addition is without doubt the best furnished hospital in the state. One of the many novelties introduced that tend to the comfort of the patients is the invention of Dr. W. H. Humiston. Instead of the numberless and annoying bells used to call the nurses and doctors that are deemed necessary in most hospitals, there has been arranged a set of electric light signals. When a patient wants to call a nurse the button is pushed and outside the door of the room a red electric light appears that gives the call. This innovation, it is expected, will add to the comfort of patients. The second floor contains twenty-six private rooms furnished by friends of the institution. The third floor contains thirteen private rooms, eight of which are still unfurnished. The fourth floor is the dormitory for the nurses, is finished in white and is spacious and airy. The training school for nurses in connection with the institution is one of the finest in the city. The free dispensary in the basement will have a capacity of treating 10,000 patients a year and 6004 were treated last year. The cost of the building was \$40,000. The entire sum was raised through the efforts of Dr. W. H. Humiston, one of the most liberal contributors being Mr. H. M. Hanna. He took a great interest in the building and gave the largest sum toward its erection. The hospital has no endowment fund and has no paid staff. The services of the manager, physicians and nurses are all free.

#### PENNSYLVANIA.

**Fraternity Charter Granted.**—A charter has been granted the Phi Beta Pi Medical Fraternity, at Pittsburg.

**Microscopic Outfit Presented.**—Mrs. Charles M. Schwab has given a complete microscopic outfit to the East End Hospital, Pittsburg.

**Marine-Hospital for Pittsburg.**—The bill appropriating \$125,000 for a United States Marine-Hospital at Pittsburg has been passed by the senate.

**Hospital Plans Accepted.**—The directors of the Allegheny General Hospital have accepted the plans for the new building, which will cost at least \$325,000.

**New Operating Room.**—The new operating room at Reading Hospital, erected at an expense of \$8000, has just been completed and equipped and was open for inspection, March 23.

#### Philadelphia.

**Gifts to University Laboratories.**—Two anonymous gifts, one of \$5000, another of \$10,000, have recently been made for the new medical laboratories of the University of Pennsylvania.

**Children's Hospital Staff.**—Dr. James P. Hutchinson has been recently elected visiting surgeon to the Children's Hospital, and Drs. Henry Norris and George M. Coates have been appointed to the dispensary surgical staff.

**To Regulate Barber Shops.**—An ordinance to regulate and improve the condition of barber shops of Philadelphia will be introduced into councils. It will provide for the licensing and registration of all shops, and for the appointment of inspectors to investigate their sanitary condition.

**Training School for Crippled Children.**—It is proposed by P. A. B. Widener, as a memorial to his wife, to erect, in a suburb of Philadelphia, a training school for crippled children. It is the plan to provide a home, hospital, and general education, but especially to give such industrial instruction as will enable this afflicted class to support themselves. The complete cost, including endowment, will be about \$2,000,000.

**The Righter Case.**—In the suit for damages, Bridget Nugent vs. Dr. H. M. Righter, the court has granted a new trial. It will be remembered that the plaintiff was recently awarded \$1000 damages, presumably for malpractice in the vaccination and subsequent treatment of her child, who died.

Among much volunteer aid in the further defense of the case, is an appropriation of \$25 by the Germantown Medical Society.

#### TEXAS.

**Railway Hospital at Houston.**—Work has begun on the Southern Pacific Hospital, Houston. The building will be two stories high, and will accommodate about 50 patients.

**Medical College Commencement.**—The medical department of the University of Dallas held its commencement exercises March 18. Hon. E. B. Mure delivered the opening address. A class of 19 was graduated. The degrees were conferred by Dr. Charles M. Rosser.

**Change of Meeting Place.**—The place for holding the next annual meeting of the Texas State Medical Association has been changed from El Paso to Dallas, and the time has been changed to May 6 to 9, inclusive. The change of time was made to avoid conflicting with the reunion of the Confederate veterans, which will be held in Dallas, April 22.

**Personal.**—Dr. Charles M. Yates and family, of Grand View, have moved to Roswell, N. M. —Dr. Mills Dennis, Temple, has resigned his position as house surgeon in the Santa Fe Hospital and has gone to the Philippine Islands as an acting assistant-surgeon in the Army. —Dr. William E. Brown, Coleman, has moved to Abilene. —Dr. William Miller, Boerne, who has been residing in California for some time past on account of his health, will shortly return to Texas to practice.

#### GENERAL.

**Cholera Situation in Manila.**—The latest news from Manila gives the total cases of cholera which have occurred to be 90, and of these 70 have died.

**Leprosy Report.**—The commission of medical officers of the U. S. Marine-Hospital Service, appointed to investigate the origin and prevalence of leprosy in the United States, has made its report to the senate. The report shows 278 cases of leprosy in the United States, as follows: Alabama, 1; California, 24; Florida, 24; Georgia, 1; Illinois, 5; Iowa, 1; Louisiana, 155; Maryland, 1; Massachusetts, 2; Minnesota, 20; Mississippi, 5; Missouri, 5; Montana, 1; Nevada, 1; New York, 7; North Dakota, 16; Oregon, 1; Pennsylvania, 1; South Dakota, 1; Texas, 3; Wisconsin, 3. Of the total number 176 are males and 102 females; 145 American born, 120 foreign born, and the remainder uncertain. The large numbers in Louisiana, Florida and California may be explained by the proximity of those states to foreign sites of the disease, but why Minnesota and North Dakota are so well supplied with lepers does not so readily appear. The commission states that only 72 per cent. of these lepers are isolated and provided for, and recommends the establishment of a retreat for lepers, preferably in the arid Southwest, on the Pacific Coast or on an island in the Gulf of Mexico. The opinion is expressed that there are more cases than are here enumerated, some cases being concealed and some unrecognized. Concerning the origin, it is stated that 186 of the cases were contracted in the United States, but the opinion is expressed by the commission that this number is too large and that some of these cases were brought from abroad. Infection is conveyed from one person to another, they believe, and the most common method of contagion is the inhalation of dust where lepers have been located.

#### Smallpox.

**Illinois:** At Carbon Cliff, 9 cases were discovered March 21. These cases had been ill for a week, but the supposition had been that they were suffering merely from chicken-pox, which has been supposed to have been the disease which has existed as an epidemic all winter.

**Chicago:** The smallpox statistics for the first three months of the year are satisfactory. During this period there were 573 cases and 118 deaths from smallpox in New York, and 106 cases and 1 death from the disease in Chicago. During the week ended March 29, 14 cases of smallpox were reported; 11 patients were discharged from the isolation hospital; 41 are still there and 19 suspected cases were investigated.

**Maryland:** There are several cases of smallpox among miners in Allegheny County, imported from Garret. There are six patients suffering with smallpox at the pest-house at Cumberland. A death from smallpox occurred at the Quarantine Hospital, Baltimore, March 27.

**Michigan:** There were four deaths from smallpox during February, one in each of the following districts: Alma village, Gratiot County; Cannon township, Kent County; Reed City village, Osceola county, and Onaway village, Presque Isle County. Two deaths were also reported from chicken-pox.

which term, with other designations, like "Cuban itch," indicates deaths from smallpox. These deaths were in Handy township, Livingston County, and Delray village, Wayne County. There were also 2 deaths from mumps, 1 in Clinton County, and 1 in Lapeer County. Smallpox was present in 145 localities during the week ended March 29.

Minnesota: Dr. Braeken, of the State Board of Health, has issued the weekly smallpox report of the State Board of Health for the week ended March 17. The report shows 254 new cases in 43 counties and 77 localities and no deaths.

Nebraska, Omaha: Dr. C. P. Wertenbaker, U. S. Marine-Hospital Service, ordered to Omaha to investigate the alleged smallpox epidemic, makes, in his report, the following recommendations: 1. A house-to-house inspection, with the prompt isolation of patients. 2. The isolation and vaccination of all persons exposed to smallpox in the disinfection of their clothing. 3. Vaccination with pure glycerinized lymph of all persons in the city that have not been successfully vaccinated within a year. 4. The prompt and thorough disinfection of all infected houses and articles. 5. That the assistance of all corporations, business firms and individuals be invoked in making general vaccination as thorough as possible. He does not consider the conditions in Omaha at all alarming. There are more cases of smallpox in the city than is desirable, even though most of them are isolated in the hospital. There has been a steady decrease in the number of cases for the past month, and this will doubtless continue as the weather grows warmer and the people live more out of doors, until it disappears. The danger of the situation lies in the fact that unless the existing cases are found and isolated and infected houses and materials disinfected, the disease will reappear again next winter and the troubles of previous years will be repeated. In this connection it is suggested that all winter clothing, etc., be thoroughly aired and sunned for several days before being packed for the summer, and that on bright, sunny days houses where sickness has occurred during the winter should be thrown open as much as possible to admit the air and sun.

Canada, Ontario: Dr. Hodgetts, the provincial health inspector, has returned to Toronto from the Ottawa district, where he has been investigating the spread of smallpox from the lumber camps. He speaks encouragingly of the outlook in Ontario generally. Dr. Bryce, the provincial secretary of the Board of Health, has been notified that several cases have occurred in British Columbia, at Rossland, Grand Forks and Fernie.

Quebec: Dr. Elliott, writes over his own signature in the Quebec Chronicle, March 26, that at present there are hundreds of cases of smallpox in the city unknown to the health office and that there is the bright prospect of having a thousand before long. Compulsory vaccination is a thing of the past and the by-law compelling employers to have their help vaccinated is also disregarded, one alderman especially being noted for not compelling his men to undergo vaccination. Placarding is done away with, the patients unable to pay the Civic Hospital dues are allowed to run loose, spreading the disease, and the Civic Hospital is useless.

Montreal: Smallpox is decreasing in Montreal. At the present time there are only ten houses quarantined, and by the latter end of the week it will be raised on most of these. There are not nearly the number of patients in the hospital that there were two weeks ago.

Manitoba: Dr. J. R. Steep, the medical officer of the Indian department, has returned from the vicinity of Bad Throat River on Lake Winnipeg. He stated that there were 73 cases of smallpox altogether among the Indians, but that strenuous measures were taken to suppress the outbreak and that these were stringently carried out, with the result that the disease is now completely eradicated, not a single case remaining, and as the prescribed period of quarantine has been passed there is no likelihood of the disease reappearing.

England, London: The epidemic of smallpox in London still shows no signs of diminution. There are 1542 cases under treatment in the metropolitan hospitals, against 1321, 1309 and 1512 in the preceding 3 weeks; 450 new cases were admitted during the week, against 502, 369 and 555 in the preceding weeks. In the metropolitan county of Essex the number of cases have considerably increased. For the weeks ending March 1, 8 and 15, the numbers are, respectively, 48, 57 and 73. In the Orsett area, which is adjacent to the smallpox ships, which are anchored in the Thames, the number of cases has decreased. It may be remembered that we recently pointed out in THE JOURNAL that Dr. Thresh, medical officer of health for the county, has conclusively shown that the ships are a

source of infection to the Orsett area and that the virus is carried from them by the air, possibly for a distance of two or three miles. The deaths from smallpox were 81, against 64, 75 and 81 in the previous three weeks. The total number of fatal cases now amounts to 845.

#### CANADA.

**Fatal Accident in Brockville Hospital.**—Miss Mary E. Jackson, 24 years of age, a nurse in training at the Brockville General Hospital, drank mercurial solution on the night of the 21st and died the following day. The bottle was labeled magnesium sulphate and she drank about two ounces. It was, however, a solution of bichlorid of mercury.

**Former Toronto and Chicago Physician Honored.**—Dr. Don. J. Armour, Toronto, 1894, who was formerly demonstrator of anatomy under Dr. Lewellys Barker, Chicago, and a son of Chief Justice Armour of Toronto, has been appointed senior assistant surgeon at the Belgrave Hospital for Children, London, England. He will also continue his duties as senior demonstrator of anatomy in University College, London.

**New Canadian Members R. C. S. England.**—*The Lancet* announces that the following Canadian practitioners have recently passed the necessary examinations to admit them to membership in the Royal College of Surgeons, England: Dr. Charles Buckingham Shuttleworth, Trinity Medical College, Toronto; Dr. Walter Henry Phillip Hill, McGill University, Montreal; Dr. Henry Ardagh Kingsmill, Western University, London, Ontario.

**Ontario's February Health Report.**—Dr. Bryce reports for February that there were 38 deaths from scarlet fever; 34 from diphtheria; measles, 21; whooping cough, 16; typhoid fever, 25; consumption, 177. The total from all causes, 2241, in 769 municipalities which reported, constitute about 90 per cent. of the population. As compared with February of 1901 there has been a considerable falling off from consumption, as a year ago there were 238 deaths from that cause.

**Six-Year Courses at McGill University.**—The corporation of McGill University has decided that the students in applied science and in medicine shall be enabled to take a double course in arts and either medicine or applied science. Under the old arrangement, students who wished to take arts and medicine had first to finish four years in the former and then four years in the latter. This made a course of eight years. Students in applied science will now be allowed the same privilege as the students in arts, that is, if they wish to proceed to the study of medicine they can first take their B.Sc. degree and then proceed to the study of medicine and thus complete both at the end of six years. In his third year the student in applied science will attend lectures in the faculty of medicine if he so elect, the subjects being anatomy, physics and histology. In the fourth year in medicine he will devote himself in addition to his studies in applied science to anatomy, physiology, histology, pharmacology and medical chemistry. At the end of the fourth he will receive the degree of B.Sc. The studies of the fifth and sixth years will be practically the same as for an ordinary course for the degree of M.D., C.M.

**Montreal's Health Menaced.**—"Ninety-eight per cent. of the European immigrants, who are prohibited from entering the United States by the American officials in Montreal, and at other points of entry along the border, are suffering from infectious diseases, which are the direct result of filth and lack of sanitary methods." This statement has recently been made by the special immigration inspector, who has charge of all the inspectors of immigration from Sault Ste. Marie to Montreal. These, being rejected by U. S. officials, are left to Montreal and other Canadian cities to look after. The two principal diseases they suffer from are trachoma and favus; and these immigrants so diseased are being dumped into Montreal at the rate of forty to fifty per week. This dumping process has been going on since last September, when the Board of Special Inquiry was commissioned by the United States Immigration Department at Washington. Canadians can hardly take any exception to the United States prohibiting the entry of these immigrants into their country, and, of course, as long as the Canadian government allows of their entry here, Montreal or some other place must suffer. The remedy lies in awakening the Canadian health authorities to the dangers menacing the whole country and its people.

#### FOREIGN.

**Hoffa Called to Berlin.**—Prof. A. Hoffa, of Würzburg, editor of the *Ztft. f. Orthop. Chirurgie*, has accepted a call to Berlin as successor to the late Julius Wolff.

**Virchow Institute at Moscow.**—The Russian government announces the foundation of a new institute for scientific research at Moscow, to be named for Rudolf Virchow.

**Japan After Mosquitoes.**—Japanese military authorities in Formosa are experimenting to determine the relation of mosquitoes to malaria and the means to combat the disease. The crusade against the mosquito will soon be world-wide.

**Retirement of Krafft-Ebing.**—Vienna has lost another of its great men. The death of Kaposi was followed by the retirement of Krafft-Ebing after thirty years' incumbency of the chair of psychiatry, etc. His leave-taking was an impressive ceremony. He will make his home henceforth at Graz.

**Cholera and Plague Situation.**—The mortality from these scourges increases at an alarming rate. In the Punjab, India, 70,000 deaths are reported in March. This corresponds with the prediction by our Indian correspondent on page 595, in the issue of March 1. The report from Arabia states that cholera has claimed 928 victims at Mecca during the week ending March 31, and 61 at Jeddah.

**Official Measures Against Fake Medicine in Germany.**—The German *Aerztliche Vereinsblatt* recently pointed out that many of the certificates published by charlatans were signed by employees of the government railroads. The minister of public works accordingly issued a decree forbidding the use of the railroad buildings for fake medical meetings, and expressing disapproval of the signing of such certificates.

**Gifts of the Munich Med. Wochenschrift.**—This standard weekly is owned and published by a board of eleven prominent members of the profession. Last year 4400 marks from the surplus earnings were distributed among various professional aid societies. This year 9300 marks were available for the purpose; 5000 marks were turned over to the Pettenkofer Memorial Building Fund, and the rest was given to various societies for the relief of widows and orphans of physicians, etc.

**Federation of French Anti-Tuberculosis Institutions.**—The seventy-six various anti-tuberculosis institutions of France sent delegates to the assembly convoked at Paris, March 16, for the purpose of uniting them all into a national federation; the success of the plan surpassed all anticipations. The "environment, the race and the moment" modify in each country the character of the measures undertaken in the campaign against tuberculosis. The sanatoria, which are the pride of Germany, owe their existence in great part to the compulsory sick insurance enforced in that country. The decrease of tuberculosis in England is due to the reforms in public hygiene of late years. France has its seaside sanatoria, its special anti-tuberculosis dispensaries, its farm colonies, leagues, unions, and its societies to promote the study of hygiene, besides a few sanatoria due to private enterprise or charity. All these institutions have become federated now with a central bureau of information and council for mutual aid. It is proposed to establish a permanent exposition of everything needful for the campaign against tuberculosis in connection with the bureau and emphasize especially its humanitarian side.

## LONDON LETTER.

### Smallpox in London.

In England 92 deaths occurred from smallpox last week; 89 took place in London, and the remaining three in the towns of Reading, Leicester and Swansea. In the London smallpox hospitals there were 1512 patients on March 8 against 1185, 1321 and 1309 at the end of the three preceding weeks; 555 new cases were admitted during the week against 390, 502 and 379 in the three preceding weeks. Thus it will be seen that the progress of the epidemic, which had considerably diminished, has again increased. Since the beginning, in August last, 4468 cases have been admitted to hospital, about one per 1000 of the population. Of these 2675 have been discharged cured and 758 have died. The experience of previous epidemics in London tends to show that the present one will continue at least through next winter, perhaps with increased activity.

### The Late Sir William MacCormac.

At a meeting of St. Thomas' Hospital and Medical School, to which the late Sir W. MacCormac was attached, it was decided to institute a permanent memorial of his connection with the institution. A committee of the members of the hospital and school was formed and already consists of 250 of St. Thomas' men. From these an executive committee was appointed to solicit subscriptions. The first object will be to arrange for the production of a bust to be placed in the central hall. The secretaries are Mr. G. H. Malsins, C. B., who accom-

panied the late surgeon to the war, and Mr. F. C. Abbott, surgeon of St. Thomas' Hospital.

### Arsenical Poisoning Inquiry.

The Royal Commission on Arsenical Poisoning has resumed its sittings under the presidency of Lord Kelvin. Dr. E. S. Reynolds, Manchester, to whom is due the credit of discovering that the contamination of beer with arsenic was the cause of the recent epidemic of peripheral neuritis in the north of England and Midlands, stated that a special lockout had been kept by himself and his assistants at the Manchester Workhouse and Royal Infirmary for symptoms which might have been caused by arsenic occurring in food or drink. With a few exceptions they had entirely disappeared. The keratosis, arsenical neuritis and pigmentation, which had been ascribed for years to the irritation of vermin in the pauper class, had very markedly lessened in frequency. Many of the arsenical patients who had died had died from phthisis, and in most of the cases cirrhosis of the liver with ascites necropsy had shown that there was also tubercular peritonitis. Dr. Reynolds said in the last 9 months he had seen a considerable number of heavy drinkers and had only seen two cases of peripheral neuritis which he attributed to alcohol. Each of these patients drank over a bottle of whisky a day, and no beer. Personally, his opinion was that alcohol would cause neuritis, but considering the large amount of spirits taken by people in this country it was one of the rarest diseases it associated with arsenic. From his clinical observation during the last 20 years, he was driven to the conclusion that the disappearance during the last seven months of so many symptoms, which were formerly ascribed to alcohol, could only be explained by the elimination of arsenic from alcoholic beverages. He also concluded that arsenic had been present in alcoholic beverages for many years, to an extent dangerous to a few drinkers specially susceptible. This arsenic was possibly from a source entirely independent of contaminated glucose.

### Experiments with Disinfectants.

The London County Council has issued a report by the medical officer, Dr. Shirley Murphy, presenting a joint report by Drs. Klein, Houston and Gordon on the result of experiments in disinfection. Of fluid disinfectants carbolic acid (1 in 5), permanganate of soda, bleaching powder and corrosive sublimate (1 in 1000) were tested. Of gaseous disinfectants formalin and sulphurous acid gas were tried. Dr. Shirley Murphy says: The typhoid bacillus was killed by all the disinfectants except Condry's fluid and bleaching powder. Condry's fluid gave a negative result in each experiment, and bleaching powder for the disinfection of wood and cloth infected with this organism failed with one hour's exposure. The bacillus diphtheria was killed by formalin and sulphur dioxide. The vibrio of cholera was in each experiment destroyed by all the disinfectants except Condry's fluid and bleaching powder. Condry's fluid was practically of negative value and bleaching powder was not always efficacious on one hour's exposure, but was successful within 24 hours. Bacillus pyocyaneus was acted upon in much the same way. It was killed in each experiment by all except Condry's fluid and bleaching powder. Staphylococcus aureus was also killed in each experiment by all except Condry's fluid and bleaching powder. Anthrax spores were only destroyed with certainty by perchlorid of mercury, the other disinfectants either failing on each occasion or being uncertain and almost invariably failing when wood and cloth were the materials to be disinfected. For tubercle bacilli, carbolic acid and perchlorid of mercury were the only disinfectants efficacious on each occasion. Condry's fluid and sulphur dioxide were of negative value and the other disinfectants unreliable. Neither formalin nor sulphur dioxide were efficacious for the wood or cloth infected with this bacillus.

### Meralgia Paresthetica.

At the Edinburgh Medico-Chirurgical Society Dr. Edwin Bramwell showed a case of this comparatively unrecognized disease. A man, aged 43, had suffered for 18 months from pain over the right hip and lower part of the right thigh anteriorly, also from a feeling of coldness on the outer side of the right thigh. The pain was greatly increased by walking and was so severe that it had incapacitated him from work. In other respects he enjoyed excellent health; he had not had rheumatism or syphilis. The condition was attributed to sleeping on hard boards in damp clothes. An area of relative cutaneous hyperaesthesia was found on the outer side of the right thigh, while there was marked tenderness over a point 1½ in. below and just external to the right anterior superior iliac spine. The symptoms were obviously referable to the right external cutaneous

nerve. Since no improvement resulted from rest in bed and Paradism the nerve was cut down upon at the level of Poupart's ligament and 3 inches excised. The nerve and its relations appeared to be normal. The pain which had previously been present even when the patient lay in bed, at once disappeared. For two or three weeks after the operation the patient complained of a feeling of tenderness on deep pressure over this area. Four weeks after operation he was quite free from pain, but still had a feeling of stiffness about the front of the right thigh. No degenerated fibers were found in the excised nerve. Dr. Bramwell considered meralgia paresthetica a distinct clinical entity, probably not uncommon, Roth having recorded 15 personal observations. The condition is well worthy of notice for purposes of exclusion in differential diagnosis when the pain is so severe as to unfit the patient for work. The pathology is obscure; perhaps in some cases there is merely neuralgia, in others neuritis. Paradism appears to have been efficacious in the treatment of several of the reported cases. Resection of the nerve is justifiable in severe and persistent cases.

## State Boards of Registration.

**Vermont Examination.**—The Vermont State Board of Medical Examiners held an examination at Burlington on January 8. The number of subjects examined in was 8; questions, 80. The applicants numbered 8, of whom 6 passed.

|         |         | PASSED.                         |       |       |  |

## Married.

R. F. CLARK, M.D., Los Angeles, Cal., to Miss Florence Sykes, at Yuma, Ariz., March 16.

C. A. CUTTS, M.D., Minneapolis, Minn., to Miss Marie Hielman, of River Forest, Ill., March 25.

FAIR ROWE BRINSON, M.D., Lithonia, Ga., to Miss Evie L. Sanderfur, of Dennard, Ga., March 18.

A. R. GILLIFORD, M.D., Allegheny, Pa., to Dr. Jane Nye, of Portsmouth, Ohio, at Cincinnati, March 20.

DICKSON L. MOORE, M.D., Columbus, Ohio, to Miss Marie Margaret Watson, of Washington, D.C., April 2.

J. H. HIGBEE, M.D., Wellsford, Kan., to Miss Daisy Guthrie, of Wichita, Kan., at Haviland, Kan., March 13.

FRANK S. JACKSON, M.D., Dunkirk, N. Y., to Miss Mary C. Crysler, superintendent of the Brooks Memorial Hospital, Batavia, N. Y., March 22.

SIAS CLINTON FREDERICK, M.D., Wilmington, Del., formerly of Baltimore County, Md., to Miss Lucretia Paschall Carpenter, at Germantown, Pa., March 19.

## Deaths and Obituaries.

**Robert G. Ellegood, M.D.** Pennsylvania Medical College, Philadelphia, 1852, one of the most prominent and wealthy citizens of Delaware; for many years a practitioner in Concord, who served his state as representative and as auditor; a member of the American Medical Association, died at his home, March 22, from septicemia, after an illness of one week, aged 74.

**Daniel W. Richards, M.D.** Jefferson Medical College, Philadelphia, 1863, one of the oldest practitioners of Easton, Pa., a surgeon in the Civil war, and a prisoner in Libby Prison, died at his residence in South Easton, March 23, from paralysis, aged 64. He was a member of the local, county and state medical societies, and of the American Medical Association.

**Rollin E. Cutts, M.D.** University of Minnesota, Minn., 1893, died suddenly from apoplexy, while making a professional call,

March 19, aged 35. He was one of the best-known physicians of Minneapolis, and was a member of the Hennepin County Medical Society, Minneapolis Pathological Society, Minneapolis Medical Club, and the Minnesota Academy of Medicine.

**Erwin J. Eldridge, M.D.** Jefferson Medical College, Philadelphia, 1854, a prominent physician of Americus, Ga., where he had resided for nearly half a century; a surgeon in the Crimean war and on the staff of Gen. Howell Cobb in the Civil war, died suddenly at his home in Americus, from apoplexy, March 13.

**Oren D. Pomeroy, M.D.** College of Physicians and Surgeons, New York, 1860, a specialist on diseases of the eye and ear, who practiced for many years in New York City and was one of the surgeons of the Manhattan Eye and Ear Infirmary, died at his home in Whitestone, L. I., after an illness of one year, aged 68.

**John E. Richardson, M.D.** College of Physicians and Surgeons, New York, 1877, who, after graduation, served as interne in Bellevue Hospital and then studied abroad for a year and a half, died at his residence in Brooklyn, March 23, from malignant disease of the throat, after a prolonged illness, aged 51.

**Paul Carlyle, M.D.** Western Reserve University, Cleveland, 1901, a promising young physician and ex-interne at Lakeside Hospital, who went to Texas soon after he was graduated, on account of lung disease, died at his home in Mount Gilead, Ohio, March 21, from consumption, aged 26.

**Gerhard Loeling, M.D.** Jefferson Medical College, Philadelphia, 1874, a German physician of prominence in Philadelphia, and a member of the Philadelphia County Medical Society, died from heart disease, March 23, after a short illness, at his residence in Philadelphia, aged 69.

**Tandy L. Dix, M.D.** Kentucky School of Medicine, Louisville, 1853, for nearly fifty years a practicing physician in Louisville and Shelbyville, Ky., but for the last three years a resident of Holly Springs, Miss., died at the home of his son in that city, March 23, aged 73.

**Uriah Gilman, M.D.** Jefferson Medical College, Philadelphia, 1861, the oldest practitioner of Woodstown, N. J., died suddenly from heart disease, March 24. He was 64 years of age and served in the Civil war as surgeon of the Twelfth New Jersey Infantry.

**Charles A. Seler, M.D.** University of Pennsylvania, Philadelphia, 1892, formerly a practitioner of Allentown, Pa., who was obliged to go to California for his health in 1899, died at his home in Hay Fork, Trinity County, from pneumonia, March 18, aged 32.

**Henry M. Bishop, M.D.** College of Physicians and Surgeons, New York, 1869, a prominent practitioner of Brooklyn, N. Y., and a member of the American Medical Association, died suddenly from apoplexy, at his home in Brooklyn, March 15, aged 65.

**George W. Cushing, M.D.** Long Island College Hospital, Brooklyn, N. Y., 1874, who had practiced at the same address in Schermerhorn Street, Brooklyn, ever since his graduation, died at his home, after a short illness, March 20, aged 53.

**Thomas S. Butcher, M.D.** Jefferson Medical College, Philadelphia, for about fifteen years a practitioner of Philadelphia, but of late years a resident of Monterey, Nuevo Leon, Mexico, died in that city from typhoid fever, recently, aged 55.

**Thomas C. Hanson, M.D.** University of California, San Francisco, 1867, vice-president of the Nevada State Board of Health and a prominent physician of Nevada, died from apoplexy, at his apartments in Winnemucca.

**Reuben O. Evans, M.D.** Tufts College Medical School, Boston, an eye specialist of Malden, Mass., died suddenly from heart disease, March 20, while examining a patient in his office, aged 42.

**Andrew G. Nywall, M.D.** Rush Medical College, Chicago, 1897, a practitioner of Chicago, died at the Presbyterian Hospital in that city, March 23, after an illness of six months, aged 30.

**Richard T. Isbester, M.D.** Tulane University, New Orleans, 1890, a member of the Chattanooga city council, died suddenly from apoplexy, at his home in Chattanooga, March 21, aged 45.

**O. B. Scott, M.D.** University of Louisville, Ky., 1888, a practitioner of Cynthia, Ky., died at his home in that place, from apoplexy, after an illness of one day, March 20, aged 43.

**George W. Bishop, M.D.** Medical College of Georgia, Augusta, 1887, a practitioner of Sanford, Fla., died at his residence in that place, from consumption, March 20, aged 35.

**Thomas L. Jackson M.D.**, Jefferson Medical College, Philadelphia, 1852, a prominent physician of Marvell, Ark., died at his home in that place, March 17, from consumption.

**H. H. Hogan, M.D.** University of Vermont, Burlington, 1863, the oldest practicing physician in Washoe County, Nev., died at his home in Reno, from pneumonia, March 17.

**Dryden Rogers, M.D.** Missouri Medical College, St. Louis, 1848, a well-known physician of Topeka, Kan., died at his home in that city from pneumonia, March 25, aged 75.

**Theodule Bolduc, M.D.**, ex-house surgeon at Notre Dame Hospital, Montreal, died from heart disease at St. Urbain, Charlevoix County, Quebec, March 20, aged 25.

**Vincent T. Hart, M.D.** Medical College of Georgia, Augusta, 1853, of Wood County, Texas, died at his home in Mineola, March 13, after a protracted illness, aged 72.

**Edward S. Oliver, M.D.**, a graduate of the Johns Hopkins University and Medical School, Baltimore, died at Saranac Lake, N. Y., March 18, from consumption.

### Miscellany.

**Examination of Ocular Fundi of Animals.**—One of the most remarkable scientific investigations of modern times is now being brought by Dr. Lindsay Johnson, F.R.C.S., to the close of its earlier stages. Some years ago he began to examine the fundi of animals and betook himself to Jamrach's collection of animals and other menageries and found the macula intea present in monkeys, but that it varied with each genus. Following up his clue, he discovered that every family of the mammalian order possessed a distinct appearance of its own in the eye, by which anyone seeing the fundus with an ophthalmoscope would be able to recognize not only the family but the genus of the animal. He then proceeded systematically to examine all the animals to be seen in the Zoological Gardens of London, Antwerp, Amsterdam, Hamburg and elsewhere; and as a result of this gigantic labor he found many new and striking facts. For instance, he realized that certain organs, such as the pecten, were also to be found in a large number of the lower mammals—rodents and marsupials. This, of itself, was an interesting piece of evidence in support of the Darwinian doctrine of evolution: his various discoveries are to be found recorded in the proceedings of the Royal Society. His method of investigation is interesting. To examine the eyes of the animals it was necessary for Dr. Johnson to darken the cage, to sit beside the animal with a lamp behind his head and to look through the ophthalmoscope at a distance of half an inch from the animal's eye, for a period of not less than two hours at a time. The total time spent over each animal would vary from eight to sixteen hours. He examined the eyes of about a thousand animals, and made drawings of about 250, some fifty of which have so far been published by the Royal Society. In the cases of the larger animals it was necessary to confine their movements. Thus the elephants were chained down. Sacks some eight feet long were made for slipping over the bears. The closed ends of the sacks were next slit with a knife and as bruin protruded his head he was promptly muzzled and lifted on to the table for the eye testing. In the cases of lions, leopards, tigers and large cats, muzzles could not be used, as they frightened the animals nearly to death. He found it advisable to cut off the whiskers of the brutes, as the touching of the whiskers during the examination made them snap. Some of the birds were induced to thrust their bills into large corks, and the fishes had to be treated gingerly to avoid their suffocation. The boa constrictors and pythons were thrown into sacks, to circumvent their squeezing propensities, and their heads were held out of the sacks by keepers; while with wolves, beavers, otters, seals and sea lions, nets were thrown over them and they were twisted in the meshes.—*Ophthalmic Record*.

#### American Medical Hero of the Franco-Prussian War.

After the surrender of Metz on Oct. 29, 1870, it was found that black typhus fever was raging among the French soldiers who had survived the siege. The Grande Place or great square of Metz was packed with railway wagons belonging to the Eastern Railway Company of France, brought within the fortifica-

tions in order to save them from falling into the hands of the Germans. During the siege these wagons had been converted into field ambulances, in which the typhus patients were placed after their removal from the hospitals. Each truck had accommodation for at least 6 patients, and as there were 320 wagons, the typhus patients must have numbered 1800. After a certain lapse of time a detachment of German soldiers entered the Grande Place in order to remove the dead for burial. A large quantity of quicklime was brought in wagons and thrown from long-handled shovels over the corpses in the trucks. The bodies were then swung by the legs into the wagons, carted away into the fields outside the walls, and thrown promiscuously into huge trenches prepared for their reception. The soil was at once shoveled over them. Among the bodies thus unceremoniously huddled into the trenches was that of a young doctor, who had volunteered to attend on the sick men in the railway wagons, and who had himself fallen a victim to the fatal malady. The pathetic story of this youth of 22, which I afterward heard from my friend Whitwell, who had it from what he considered to be a reliable source, deserves mention as a remarkable instance of magnanimous self-sacrifice and courageous devotion to duty. He was a medical student of American nationality, unknown to me even by name. He had served in the French army as a surgeon throughout the campaign, and had been shut up with it during the siege of Metz. When the black typhus patients had been conveyed out of the hospitals into the railway wagons in the Grande Place, and no surgeon or nurse was found willing to be shut up entirely with them in the square, he volunteered to go alone into the enclosure to undertake this dangerous duty. As a medical man he knew perfectly well he was taking his life in his hands in thus devoting himself to the care of these men, who were dying of the most terribly infectious of all forms of fever. All that one pair of hands could do to relieve their sufferings he did for them by night and day, literally handing them the cup of cold water in the name of a disciple; for it is to me inconceivable that any less motive could possibly induce a youth of 22 to undertake so dangerous a task than the love of Christ constraining him. Naturally, in a short time the fever seized him in that hotbed of disease and ended his brave young life. Buried undistinguished among the heaps of corpses thrown indiscriminately into the trenches no storied urn or animated bust reared over that nameless grave to commemorate his noble self-sacrifice in the service of his fellow-beings—he remains in my memory and in that of my companions who knew the story—to be distinguished as the one true hero of the siege of Metz.—*Brit. Med. Jour., from Jones' "Quaker Campaigns in Peace and War."*

### Association News.

#### The Pathologic Exhibit.

The Committee on Pathologic Exhibit has issued the following circular: The Committee on Pathologic Exhibit for the American Medical Association is anxious to secure materials for the coming session at Saratoga, June 10 to 13, inclusive. This exhibit was accorded much praise and comment during the sessions at Atlantic City and St. Paul, respectively, where were collected valuable exhibits from all parts of the country. The materials included not only pathologic specimens but the allied fields, bacteriology, hematology, physiology and biology were well represented.

It would also be desirable to secure exhibits of new apparatus, charts, etc., used by teachers of pathology and physiology in medical colleges.

This exhibit has already become a permanent feature of the annual sessions of the American Medical Association, and the Committee is desirous of securing its list of exhibits as early as possible and to this end asks those having desirable materials to communicate with any member of the Committee.

To contribute to the value of the work, it is suggested that as far as possible each contributor select materials illustrative of one classification and by such specialization enhance the usefulness of the display.

Those lending their materials may feel assured that good

care will be given their exhibits while in the hands of the Committee and due credit will be given in the published reports.

Very respectfully,  
F. M. JEFFRIES,  
214 E. 34th Street, New York City.  
W. A. EVANS,  
103 State Street, Suite 1403, Chicago, Ill.  
ROGER G. PERKINS,  
West. Res. Med. School, Cleveland, Ohio.  
Committee on Pathologic Exhibit, Am. Med. Association.

**Physicians' Club of Dayton.**—The physicians of Dayton have organized a club, embracing all schools, which is to meet five times a year. Dr. Horace Bonner is chairman.

**Association of Medical Officers of the Army and Navy of the Confederacy.**—This Association will meet under the presidency of Dr. D. D. Saunders, Memphis, Tenn., at Dallas, Texas, April 22.

**Physicians' Club of Newark, N. J.**—The annual meeting of this Club was held, March 14, at which Dr. Charles L. Hill was elected president; Dr. Charles H. Randall, vice-president, and Dr. William Petry, secretary and treasurer.

**Noble County (Okla.) Medical Society.**—The physicians of Noble County held a meeting in Perry and organized a medical society, with Dr. Samuel A. Moore, president; Dr. R. A. Felt, vice-president, and Dr. Fred F. Jones, secretary, all of Perry.

**Pawtucket (R. I.) Medical Association.**—The annual meeting of this body was held, March 20. The election of officers resulted as follows: Dr. Charles H. French, president, and Dr. William F. Gillan, secretary. A banquet followed the business meeting.

**Aberdeen District (S. Dak.) Medical Society.**—At the annual meeting of this Society in Aberdeen, March 19, Dr. Francis M. Crain, Redfield, was elected president; Dr. Robert D. Alway, Aberdeen, vice-president, and Dr. Henry J. Rock, Aberdeen, secretary.

**Stark County (Ohio) Academy of Medicine.**—This organ-

ization held its annual meeting at Massillon, March 18, and elected Dr. Rezin J. Pumphrey, Massillon, president, and re-elected Dr. Esther M. Tyrrell, Canton, secretary, and Dr. Frank E. Hart, Canton, treasurer.

**Nashville Medical and Surgical Association.**—This body, composed of the colored physicians, dentists and pharmacists of Nashville, met, March 17. Dr. John A. Lester was elected president; Dr. Henry T. Noel, vice-president; Dr. Charles O. Hadley, secretary, and E. B. Jefferson, treasurer.

**Alumni Association of Fort Wayne (Ind.) Medical College.**—At the annual meeting of this body in Fort Wayne, March 18, the following officers were elected: Dr. James B. McEvoy, Fort Wayne, president; Drs. Oliver T. May, Monroeville and A. H. MacBeth, vice-presidents, and Dr. Mary A. Whery, Fort Wayne, historian.

**Johnson County (Texas) Medical Society.**—At the annual meeting of this Society, March 20, at Cleburne, the following officers were elected: Dr. T. E. Edwards, president; Drs. Larkin L. Harris, Cuba, and John M. Huddleston, Cleburne, vice-presidents, and Dr. Finis D. Beauchamp, Pleasant Point, secretary.

**Central Michigan Medical Society.**—At the annual meeting of this Society, held in Lansing, March 13, Dr. Sidney H. Culver, Mason, was elected president; Dr. Harry A. Haze, Lansing, vice-president, and Dr. L. Anna Ballard, Lansing, secretary and treasurer. The meeting was followed by an anniversary banquet.

**Vanderburg County (Ind.) Medical Society.**—This Society held its monthly meeting, March 18, at which Dr. J. Herbert Willis was elected president; Dr. Ben S. Rose, vice-president, and Dr. Wm. Ruston Davidson, secretary and treasurer, all of Evansville. The Society is making elaborate preparations to entertain the Indiana State Medical Society, May 22 and 23, at which Dr. Victor C. Vaughan, Ann Arbor, will be the guest of honor.

**Western Alumni Association of the University and Bellevue Hospital Medical College.**—The second annual meeting and banquet of this Association were held at the Sherman House, Chicago, March 22. The program included responses to toasts from Drs. Edward W. Jenks, Detroit; David W. Graham, Chicago; James C. Culbertson, Cincinnati; Dorrance W. Aldrich, Galesburg, Ill.; George N. Kreider, Springfield, Ill.; Emerson M. Sutton, Peoria, Ill.; Arthur R. Reynolds, Chicago; and James F. Percy, Galesburg, Ill. The following officers were elected: President, Dr. George N. Kreider; vice-presidents, Drs. James C. Culbertson and George W. Mahoney, Chicago; secretary-treasurer, Dr. Willis O. Nance, Chicago; members of executive committee, Drs. Benjamin F. Urau, Kankakee, Ill.; James F. Todd, Chicago; J. Sanderson Christison, Chicago; David W. Graham, Chicago; and Paul Caspers, Chicago.

### NORTH BRANCH OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

*Meeting held March 20, 1902.*

The President, Dr. A. M. Eaton, in the Chair.

#### Ovarian Disease as a Factor in Pseudo-cyesis.

DR. J. THOMPSON SCHELL gave a brief résumé of the literature on this subject and in all but one instance the cause of this condition was assigned to the mental state of the patient. Dr. E. N. Chapman, in 1864, suggested the possibility of irritation of the uterus and amenorrhea. Four cases which have occurred in the author's own experience were then reported, and in each of these instances there had been some history of ovarian disease. Their ages varied from 28 to 33 and all had previously borne children. All these cases during the early period of the supposed pregnancy had presented the typical symptoms thereof, such as nausea, cessation of menstruation and enlargement of the abdomen and breasts, and in every instance was the patient firmly convinced that she felt the movements of the child. In the first case the patient, after having been in labor forty hours, under the care of her attending physician, was removed to the hospital, and upon examination under ether was found not to be pregnant. A curettage was done, resulting in the removal of some shreds of endometrium, and the patient was discharged from the hospital twelve days later, since which time she has complained of symptoms indicating pelvic involvement, but as she refuses

to be examined this can not be definitely stated. Case No. 2, after missing several periods, again began to menstruate and upon examination under ether a curettage was made, after which the patient made a good recovery, although she still suffers from irregular and painful menstruation, backache, leucorrhea and pains and tenderness in the left ovarian region. The third case was a markedly neurotic patient, and as in Case No. 2, upon menstruation recommencing, she was examined under ether and curettage performed, after which she made a good recovery, although she has subsequently suffered somewhat from nervousness, nausea and backache. Case No. 4 presented practically the same symptoms as the previous ones, and as in Nos. 2 and 3, an examination under ether was made and a curettage done, a quantity of diseased endometrium being removed. This patient made an uninterrupted recovery. Attention was called to the fact that in none of these cases could the condition be based upon the theory of the menopause being a factor, as all were far below the age of this period. Neither did it seem that any of them were either very desirous or very averse to becoming pregnant. While the author does not attempt to overthrow the theory that pseudo-cyesis is the result of a mental condition, yet he suggests the possibility of ovarian disease being a factor in the production of the mental state.

DR. JOHN G. CLARK, in discussion, divided the cases of pseudo-cyesis into three classes: 1, those that fear pregnancy; 2, those that expect to be pregnant; and 3, those that especially desire to be pregnant. In the first class, the missing of one or two menstrual periods will often fix the delusion of pregnancy in the woman's mind, especially when the fear is superinduced by previous illicit intercourse. The second class usually occurs in the married woman who goes along in the ordinary course of events expecting to be pregnant and, of course, the missing of one or two periods firmly fixes this idea in her mind. The third class is generally observed about the age of the menopause and generally occurs in women who have previously had no children, the patient oftentimes being a typical society woman, who has in the early part of her life done everything to avoid conception and, in some instances perhaps, even terminated pregnancy artificially. The opinion was expressed that the symptoms in these cases are of a mental rather than a physical nature, but it was also suggested that possibly this mental condition might be caused by disease of the genital organs and this possibility was strengthened by the fact that in many cases where insanity has occurred co-existent with ovarian disease, the removal of the latter condition cured the former.

DR. CHARLES P. NOBLE stated that out of about 150 cases of this condition which had come under his observation, the large majority had been observed in patients who were especially desirous of being pregnant. Contrary to the opinion expressed by Dr. Clark, he believes that most of these cases occurred in women below the age of the menopause. In regard to the fear of pregnancy being a cause, he stated that, aside from those who had had illicit intercourse, he did not recall having ever seen a case. Although he has seen a few cases in which ovarian disease was associated with this condition, yet he inclines to the opinion that it is caused by a mental rather than a physical disturbance.

DR. MORDECAI PRICE stated that in his experience most of the cases of this disease had occurred in neurasthenic women, and in many instances the patient was quite fleshy. While he views the mental condition as the immediate cause, he also feels that this condition is often produced by some disease of the genital organs. Several cases have also come under his notice where both the attending physician and the patient were convinced of the existence of pregnancy, when the real trouble was a large fibroid or ovarian tumor.

#### The Treatment of Puerperal Eclampsia.

DR. WILLIAM E. PARKE reported a case and dwelt in considerable detail upon the etiology and treatment of this condition. This patient had been twice pregnant, the first pregnancy being terminated about the eighth month on account of convulsions, of which four occurred before the delivery of child and none followed. The patient apparently made a good re-

covery and repeated examinations of the urine failed to reveal the presence of albumin. During the second pregnancy her health remained good until the seventh month, at which time there was edema of the ankles, albumin was present in the urine and the quantity passed in 24 hours was very much lower than normal. Five days after the onset of these symptoms she complained of a pain between the shoulder blades for which a hot bath followed by rest in bed and hot packs were recommended. A pill containing calomel and podophyllin was also ordered. The attending physician had scarcely left the house after prescribing the above treatment before the onset of a convulsion, and a physician was called in the emergency who administered morphia hypodermically. Two hours after his first visit the attending physician returned and finding that five or six convulsions had occurred, forced delivery under anesthesia. Prior to delivery venesection had been performed, and immediately following, 10 minims of Norwood's tincture of veratrum viride was administered hypodermically. The pulse rate at this time being 130, the same remedy was administered in 5 minim doses at half-hour intervals until the rate was reduced to 60, at which time the frequency was reduced to two, three and six hours, according to indications. In addition to the above treatment, 3 drops of croton oil on sugar was placed on the tongue and an ounce of magnesium sulphate injected into the rectum, followed later by enemas containing 30 grains of chloral and 60 grains of bromid. The patient made fairly rapid recovery. Great stress was laid on the importance of closely watching the patient during the period of gestation, in order to prevent the formation of the toxic agents from forming in the blood, and if they are already present to eliminate them. For increasing the activity of the skin, hot baths and hot packs were recommended, and for stimulation of the renal function increased consumption of water, Basham's mixture and in more urgent cases one grain each of calomel, squill and digitalis, twice daily, was suggested. Where the pulse is of high tension nitroglycerin was considered of service. If, notwithstanding these preventive and curative measures, the renal insufficiency continues and toxemia increases, forced delivery is advised. For the treatment of the convulsions, venesection, withdrawing 12 to 20 ounces of blood, according to indications, inhalations of chloroform, administration of veratrum viride, chloral and bromid and injections of salt solution, either through the veins or by the bowel, were recommended.

DR. JOHN G. CLARK said that it is probably due to the retention of some poisonous product within the body. Experiments on rabbits have developed the fact that the introduction of any drug or the application of the electric current will produce convulsions much more quickly in the pregnant than the non-pregnant animal. The toxemic process may be produced by the defective working of the kidneys, liver, skin, etc., and while it was formerly supposed that there were no pathologic lesions in eclampsia, recent experiments have revealed the fact that in 73 out of 75 cases of this condition distinct pathologic changes had occurred in the vital organs.

DR. CHARLES P. NOBLE recommended, as a remedy for the convulsions, blood-letting followed by the injection of salt solution into the veins in the case of vigorous patients. Chloral was thought to be good, but should be used with caution, while morphia and pilocarpin were not approved, the former owing to its contra-eliminating powers and the latter owing to its increasing to an abnormal extent the secretion of all the fluids of the body. In treating these convulsions the proper course was to relieve the convulsion and then set about the delivery of the child, rather than to direct the whole attention to either end.

DR. MORDECAI PRICE recommended that the attention be first directed to the convulsions, stopping them, if possible, before setting about the delivery of the child. For this purpose he considers venesection the most beneficial measure. Chloroform is of little value, as its effect is not lasting; morphia and pilocarpin were not recommended and chloral was thought to require great caution.

DR. WILHELM KRIESEN stated that in his opinion the urine should not be examined for albumin alone and recommended a careful urea estimation in all cases. Among the various

methods of treatment mentioned were the different drugs which had been recommended by the previous speakers, hot packs, venesection and the substitution of salt solution, and the injection of the salt solution by means of the bowel. Prompt delivery was recommended in all cases.

DR. ANDREW J. DOWNES considered that the most necessary thing in the treatment of puerperal eclampsia was prompt delivery; the difference in the mortality between the cases which he has observed in private practice and in hospital work he attributes to this cause. He recommended the use of morphia or chloroform to stop the convulsions, followed by immediate delivery.

### NEW YORK OBSTETRICAL SOCIETY.

*Stated Meeting, Held March 11, 1902.*

The President, Dr. Malcolm McLean, in the Chair.

#### Puerperal Tubo-ovarian Abscess Resembling Appendicitis.

DR. HERMAN J. BOLDT presented this specimen. From the conditions found during examination prior to operation the diagnosis of appendicitis with a large perityphlitic exudate presenting some unusual features was made. What was thought to be a perityphlitic exudate was found to be a tubo-ovarian abscess. The upper part of the tube was firmly agglutinated to the intestines. An unusually long appendix vermiformis, 12 cm., was found intimately adherent to the posterior surface of the tube.

DR. SIMON MARX had seen a number of cases of appendicitis occurring during and after pregnancy and he had become very wary about making a diagnosis between appendicitis and tubo-ovarian abscess. A diagnosis of that kind might be offered because of the subinvolution, or enlarged uterus.

DR. HERMAN J. BOLDT showed a case of "Chronic Catarrhal Appendicitis: Persistence of Pain After Appendectomy," that demonstrated that long persistent pain, caused by pathological changes in an organ, does not cease as soon as the pathological factor has been removed.

He also presented a specimen of an ovarian tumor which had its origin from the ovary and reached to two-fingers' breadth above the umbilicus. He neglected his usual plan of making the incision long enough at the start to remove the tumor unopened, believing that the size of the tumor could be lessened by the use of the trocar and cannula; the result was that he soiled the peritoneal cavity with the pseudo-mucinous contents. While such a mishap was not likely to endanger the prognosis from infection if the flushing is done thoroughly, still more time is consumed, the intestines are subjected to more traumatism, and there is a chance of metastasis from such material as has been clinically demonstrated. It would have been better technique to deliver ovarian tumors unopened unless one was perfectly sure that the contents were serous.

He likewise presented a specimen of "Large Colloid Tumor in a Girl of 16 Years; Doubtful Diagnosis Until Anesthesia was Administered; Twisted Pedicle; Torsion of Uterus." The tumor was ovarian, extending nearly to the xiphoid cartilage; it had a pedicle with a 360-degree twist; the body of the uterus was twisted upon the cervix at 90 degrees. While torsion of the pedicle was not uncommon in instances of ovarian tumors, a combination of pedicle and uterine torsion, in a tumor as large as the one presented (weight 8.5 kilo) was very rare. The tumor was found to be a multilocular pseudo-mucin cystoma.

#### Vaginal Hysterectomy for Hemorrhage.

DR. BROOKS H. WELLS reported this case as an argument in favor of the removal of the uterus when conditions necessitate the removal of the appendages on both sides. The specimen shown was that of an apparently normal uterus with an atrophic mucous membrane.

DR. HIRSH H. VINEBERG said that in cases of uncontrollable uterine hemorrhage an endarteritis was often localized in the terminal vessels in the uterine tissues. Several such cases had been published abroad and a few in this country.

DR. EGBERT H. GRANDIN did a suprapubic hysterectomy for

uncontrollable hemorrhage recently because the appendages were adherent high up. Upon section of the uterus a soft mass was found at the fundus, so situated that the curette would pass over it and not scrape it off.

DR. MALCOLM McLEAN said it was dangerous to attribute to the menopause any hemorrhage which was due to functional changes. Hemorrhages may occur at that period without there being present any organic condition to explain it. The case reported by Dr. Wells could be classed under that head, where the menopause had been established artificially; this resulting hemorrhage he considered to be quite rare.

DR. ABRAM BROTHERS presented a specimen of "Spontaneous Expulsion of a Cervical Polyp," because, in his experience, polypi spontaneously expelled were among the rarest of occurrences. The pedicle was one and a half inches in length.

DR. JAMES N. WEST reported the history of a case of supposed cervical polyp, but which proved later to be sarcomatous. About two months after he last saw her she fell into the hands of Dr. Janvrin, when she had sarcomata of the shoulder and under the breasts and metastasis.

#### Pathogenesis and Therapeutics of Puerperal Eclampsia.

DR. GEORGE T. HARRISON said that it was now proven that all the theories which were based exclusively upon the disturbances of the kidneys were no longer tenable. When an attack of eclampsia has broken out the indications were, 1, to lower the excitability of the brain by narcotics; 2, to cut off the effects of the centripetal irritants starting from the sexual organs, by as speedy an ending of the birth as possible, consistent with safety to the maternal organism; 3, to counteract the effect of the toxemia by restoring the function of the kidneys as quickly as possible, and by producing elimination through other channels. Another indication, according to Barnes and other authorities, is to lower the arterial tension. Lately, an Italian physician reports that in 18 cases of eclampsia he obtained brilliant results by the use of veratrum viride, 17 recovering. In the fatal case he could not attribute death to eclampsia. To meet the first indication, hypodermic injections of morphin, carefully watched, should be given. Hydrate of chloral has been highly recommended, but its use should be attended with caution especially when there is a weak heart. Chloroform should not be used for any length of time; its prolonged use was dangerous as it invariably leads to fatty degeneration of the heart and other organs. Blood-letting he did not employ; when edema of the lungs threatened in a strong woman a copious venesection was perhaps permissible. Others recommended the use of salt solution infusion with, or without, blood-letting, to dilute and eliminate the poison. To meet the second indication all were agreed that if the birth could be ended without risk to the mother, by forceps, by version, or by craniotomy if the fetus was dead, that it should be done while the patient was under an anesthetic. This presupposed that the os was already dilated, or readily dilatable. If the os is not yet sufficiently dilated, or if the cervix maintains its form and is unyielding, the question is still a mooted one as to the indication. On the one hand there are those who insist that we should wait patiently until sufficient dilatation has taken place before actual intervention, keeping the patient meanwhile under the influence of narcotics. Again, there are others who, in cases in which the cervix is dilated above, but the os undilated, make deep incisions into the cervix, the vagina and perineum and then deliver by operative intervention; when the cervix still maintains its form, they introduce a colpenynter, or Barnes' dilator into the cervix. Dührssen expresses the hope that the classical Cesarean section, in eclampsia, will be replaced soon by the vaginal. The favorable effect of the operative evacuation of the uterus in eclampsia is clear from the fact that, according to his statistics, the disease was relieved in 93.75 per cent. of the cases, while this, in spontaneous birth, is the case in only 78.9 per cent. He recommends, therefore, the Cesarean section per vaginam in maintained cervix and in dilatation of the supravaginal part of the cervix, on the contrary, the delivery with the aid of deep cervical incisions. To fulfill the third indication profuse diaphoresis should be excited by the hot pack to eliminate toxic matters. In convalescence the patient should be carefully watched, diaphoresis and

diuresis promoted, and the milk diet enjoined. The psychoses which occasionally follow, and which manifest themselves in the form of great psychical excitation and even maniacal attacks, demand careful attention.

DR. SIMON MARX did not think that Dr. Harrison laid sufficient stress upon the particular factor which exists in these cases, viz., the diminution in the amount of urea excreted. In those cases where we do not get any pathologic evidences in the urine, such as albumin or casts, there is one of two conditions present: 1, a true toxemia of pregnancy, or 2, mechanical pressure upon the ureters. This latter point had been referred to by Herzfeld in his analysis of 100,000 cases of labor, among which there were 100 cases of eclampsia; among the fatal cases, 11 per cent., not one was due to any organic trouble but all were due to mechanical cause, viz., pressure upon the ureter; there was a bilateral hydronephrosis due to pressure upon the ureters at that point where they passed over the brim of the pelvis. Regarding the treatment, he had yet to see a case, with the excretion of urea diminishing day by day, with the symptoms of intoxication present, that did not demand the induction of premature labor.

DR. GEORGE L. BRODHEAD thought that the treatment should be directed to the kidneys just as if we had to deal with an acute nephritis without the existence of pregnancy. His experience led him to believe that the first stage of labor in cases of eclampsia proceeds very slowly and that much valuable time is lost when active measures are not adopted looking towards full dilatation of the cervix.

DR. EGBERT H. GRANDIN said he had ceased to be afraid of albuminuric patients; women with albumin and casts in the urine, and who are edematous, frequently go on to term and through labor without eclampsia. If, on the contrary, women with no albumin and few or no casts, with urinary insufficiency, with an absolute diminution in the amount of urea excreted, notwithstanding that they are under the recognized dietetic and medicinal treatment which aims to keep the liver, the intestinal canal and the skin active, if, under such precautions, the kidneys remain insufficient and the urea remains below the normal, then he thought we should not wait for eclampsia to occur, but empty the uterus. *Veratrum viride*, in his hands, had been a failure; convulsion followed after convulsion, although the pulse was kept below 40. If we elect to lower the arterial tension, venesection was the method *par excellence*. When we were face to face with a long rigid cervix, Cesarean section may be indicated under ordinary circumstances; but the one method which offered itself, was not the *accouchement forcé*, but the *elective accouchement*; no force is used, the muscle yielding to pressure applied by the hand.

DR. R. A. MURRAY believed in the ingestion of large quantities of water in order to get the kidneys to throw off the waste matters.

pleasant taste; 2, by their small bulk, so that they can be given without overloading the digestive tract; 3, by their not being irritative to the digestive organs, even after prolonged use; 4, by their ready utilization in the metabolism, which can only be determined by experiment; 5, by their low price. These desiderata are fulfilled by a number of preparations now on the market, the difficulty for the practitioner to choose the best ones is increased by the misleading advertisements of the manufacturer. In his choice he should never be guided by them, but rely on analyses and trustworthy clinical reports. The albumoses (somatose) can not be administered in doses sufficient to maintain the nitrogen equilibrium, but in small doses have nutrient value and are powerful digestive stimulants. The peptones, on account of their bitter and unpleasant taste and their irritating properties to the digestive organs, can practically be abandoned; the value of the large number of other predigested foods being also, to say the least, doubtful. Meat extracts and liquid beef preparations can be used as valuable appetizing additions to the diet, but not on account of nutritious elements contained in them.

#### Heart Failure in Pneumonia.

DR. N. S. DAVIS, SR., contributed a paper entitled "Does Heart Failure Constitute the Chief Danger in Pneumonia and the Acute Infectious Fevers? Or Does the Importance Attached to it by Recent Authors Unduly Divert the Attention of the Practitioner from Other Important Pathological Conditions of the Patient?" That "progressive cardiac weakness is the most important enemy to fight in pneumonia," and the important infectious fevers, is, in substance, a declaration found in nearly all the text-books and systematic works on the practice of medicine published during the last fifteen years. During two decades preceding, we were told with almost equal unanimity that the chief point of danger in the same diseases was pyrexia or high temperature. Then, antipyretics, both internal and external, were set forth as the chief and most reliable remedies for combating the pyrexia and ensuring the safety of patients, just as we are now told that direct cardiac tonics, as alcohol, strychnin, digitalis, etc., must be our chief reliance for sustaining the action of the heart until nature and time can cure the disease. The author has seen several cases of severe pneumonia, typhoid fever and diphtheria, in which the patients had been for several days taking from 10 to 16 ounces of whisky or brandy every twenty-four hours, with three hypodermic injections of strychnia, and liberal doses of digitalis, all for the sole purpose of strengthening the heart, and without the slightest reference to the special pathologic conditions in each case causing the heart to be weak.

The most efficient mode of sustaining the strength and activity of the heart and of all other muscular structures is to supply them with freely oxygenated blood, the efficient circulation of which not only increases the leucocytic or phagocytic activity, but also best sustains the efficiency of the secretory and eliminating functions of the living body, and thereby either destroys or eliminates all disturbing or toxic agents. All pathologic conditions that diminish the amount of air received into the air cells of the lungs, and thereby diminish the interchange of oxygen for carbon dioxide, notably impair the strength of all muscular structures, both voluntary and involuntary, and consequently diminish the systolic force of the heart and the efficiency of the circulation. Dr. Davis is satisfied that nearly all the cases of serious cardiac weakness or heart failure met with in practice are caused either by deficient oxygenation and decarbonization of the blood, impairment of the action of the cardiac and vasomotor nerves, or direct degenerative changes in the muscular structure of the heart itself. The most rational and important indications for treatment in established cases of pneumonia, diphtheria, typhoid and other infectious fevers are to aid nature's own processes by securing for patients abundance of fresh pure air, strict cleanliness, free sponge bathing, pure water for drink, and the use of such diaphoretic, diuretic, and alterative medicines as will prompt, at least, natural activity in all the excretory structures of the body. It is equally important to avoid the giving of all such antipyretics and so-called cardiac stimu-

#### CHICAGO SOCIETY OF INTERNAL MEDICINE.

##### Regular Meeting.

The President, Dr. Edward F. Wells, in the Chair.

##### Modern Dietetic Preparations.

DR. ARNOLD C. KLEBS directs attention to the great progress made in this line and especially in the manufacture of nutrient preparations. In this country the progress in the manufacture has not held pace with the advances of physiologic chemistry and most of the preparations are of foreign make. He warns against the practice of taking as fact the manufacturer's exaggeration of the value of his preparation. Many of the preparations so advertised furnish at a relatively high cost an astonishingly small food-value and frequently have only a *raison d'être* on account of their stimulating qualities, produced by a higher percentage of extractive substances and salts or by the addition of alcohol.

The dietetic value of a good preparation is determined chiefly by its actual food-value, determined by the amount of assimilable albumin it contains. The price of such albumin should not be higher than that contained in ordinary foodstuffs. Possible objections against the prolonged administration of such preparations should be overcome: 1, by their having none or a

lants as are known to diminish hemoglobin and free oxygen in the blood, and to lessen both tissue metabolism and excretion. By their anesthetic and analgesic effects, they allay pain, quiet restlessness, lessen the pyrexia temporarily, but directly favor the retention of the toxic agents in the blood until an unexpected fatal collapse ensues which is attributed to heart failure. Though he has practiced medicine many years, he has never seen a case of fatal heart failure while that organ was supplied with well-oxygenated arterial blood, and the metabolic and excretory functions were fairly active. But he has known many cases of both acute and chronic disease in which death resulted directly from both respiratory and cardiac paralysis, preceded by deficient internal distribution of oxygen and lessened activity of both tissue metabolism and excretion, while they were under the persistent influence of anesthetic and narcotic drugs.

DR. GEORGE W. WEBSTER said that all those who had had a large experience in the treatment of pneumonia must give, in very many cases, an affirmative answer to the question of Dr. Davis. He meant by this, that in many cases of pneumonia heart failure was the particular symptom which demanded immediate attention. Pneumonia was not merely a disease of the lung, but was a general infection; that as the result of this general infection toxins were produced which had their action upon the intrinsic and extrinsic nerves of the mechanism of the heart and of its musculature, thus acting upon both in a deleterious way. The musculature of the heart was less able to cope with its ordinary work; the nervous influences were obtunded by the toxins, and in addition to the poisoning of the heart by toxins and want of control by the nervous system, at the same time the work of the right heart was increased. In many cases of pneumonia, as the result of overwork of the right heart, with impaired nutrition and poisoning both of muscle and nerve, its work was imperfectly done. Those who were in the habit of watching the pulmonic second tone of the heart in pneumonia were well aware that in the early stages of the disease this tone was accentuated because of the increased pressure in the pulmonary circuit, which meant the right ventricle as its work increased and its successful coping with the additional burden imposed upon it. Furthermore, as the pulmonic second tone was watched, and often it became weakened hour by hour and day by day, it was known that the general condition of the patient was not as good as it was the day before, and that this was a guide to the actual condition of that patient, not as to the temperature, or the character of the pulse, but the degree of accentuation or character of the pulmonic second tone. He was in the habit of watching carefully the pulmonic second tone in cases of pneumonia. If physicians watched this point carefully, guarded it thoroughly, as the pulmonic second tone became weakened use appropriate remedies in the way of strychnia, carbonate of ammonium, oxygen inhalations, digitalis and camphor, graduating these reasonably according to the indications, giving no more than is necessary, and withholding or increasing them as the indications arose, they would be able to save many more cases of pneumonia. In many cases of pneumonia failure of the right heart was a dangerous symptom, and one which should be more carefully guarded than almost any other symptom, particularly in acute lobar pneumonia.

DR. JOHN A. ROBISON expressed himself as a firm believer in the efficiency of oxygen in whiffs in pneumonia. His belief had been strengthened by the clinical results he had obtained. He had had several cases in which the remedy proved to be one of such potency that he believed it saved the lives of many patients. An interesting point was as to how much oxygen was actually absorbed by these patients. That there was some absorbed was proven by the action of the remedy. He recalled particularly one case, a man, 62 years of age, who had been suffering from chronic bronchitis for several years, who was attacked by lobar pneumonia. He did not see the patient in the early part of his sickness, but was called when the man was in a very low condition. He had been given the customary treatment of strychnia, digitalis, carbonate of ammonium, etc., and was in an extremely precarious state. Cyanosis was

marked; respirations were very rapid and shallow. He advised the use of oxygen, and within a few hours the man's condition improved markedly. The respirations became deeper, were not so rapid, and the cyanosis had materially diminished. The stupor which the patient had for several hours became less, and in the course of 48 hours the patient began to improve, and finally made a complete recovery. This was a simple illustration of several cases he had treated by inhalations of oxygen. The evidence as to its efficacy was so complete that physicians should have no hesitation in recommending oxygen as a good remedy.

As to the antipyretic treatment, where the antipyretic was used with the idea that it was the hyperpyrexia that was the source of danger, he thought the criticism of the essayist was a just one. Nevertheless, the use of cold water, cold sponging or ice-bags in such cases had a beneficial effect, not by lowering temperature, but by the effect it had upon the nervous system.

DR. ARNOLD C. KLEBS agreed with the essayist as to the necessity of free ventilation in cases of pneumonia. As to inhalations of oxygen, he thought the consensus of opinion of the profession, after a perusal of the literature, was against the use of this agent. Personally, he had found that it became a sort of necessary evil to be employed in every case of pneumonia. When the patient and his family believed in it, a tank had to be procured and oxygen used for its mental effect. His experience had been contrary to that of Dr. Robison. He had never seen oxygen inhalations diminish cyanosis markedly. He mentioned one case where he did not observe any effect whatever from oxygen inhalations, either on respiration or the heart's action.

DR. ROBISON thought Dr. Klebs was mistaken as to oxygen being discarded as a therapeutic agent or was not recommended; nearly all the recent text-books advised its use. Roberts of London was a strong advocate of it. He argued against its use indiscriminately, and personally he did not use it in all cases.

DR. FRANK X. WALLS had seen oxygen given where it had benefited the patient materially; in other cases, it had been given without benefit. He thought the negative results from the use of oxygen inhalations were either due to the oxygen having been improperly administered, or having been taken by the patient improperly.

DR. FRANK S. CHURCHILL mentioned a case which he had seen in connection with Dr. Klebs to whom oxygen was given in every conceivable way, without benefit. He had seen patients where the administration of oxygen seemed to improve color very decidedly, and to lessen cyanosis. However, he expressed himself as being a little skeptical as to its value. He thought the great improvement in the case narrated by Dr. Robison might have been due to the crisis which took place at the time the oxygen was given.

#### Pneumococcic Arthritis.

DR. JAMES B. HERRICK read an abstract of a paper on pneumococcic arthritis. He referred to the rarity of this condition, which occurs most frequently as a complication of acute croupous pneumonia. Cave, who reported a case in January, 1901, was able to find only 31 cases recorded in the literature. To this number Dr. Herrick added 7, 3 of them being cases that had come under his own observation. These cases tended to confirm what had been previously observed by Leroux and others, showing that the condition was most frequently met with in the larger joints; that it rarely occurred except as a complication of pneumonia; was most likely to appear late in the disease or during convalescence. The influence of trauma was shown by the records of two cases.

The prognosis was in general bad, because the condition occurred in those who were already ill of a serious disease, and because there was in these cases a pneumococcic septicemia, frequently with other localization in structures more vital than the joint. Death in many of these instances was due, not to the involvement of the joint, but to a co-existing empyema, endocarditis, pericarditis, or meningitis. The treatment to be employed would generally be surgery, yet some cases, particularly those in which the fluid in the joint was not purulent,

made good recoveries under simple aspiration. Two such cases were reported by Dr. Herriek, in one of which, where there had been an involvement of the elbow joint, the fluid withdrawn by aspiration was distinctly purulent. A recovery had followed in both of these instances. He compared relatively the benign course of pneumococcic arthritis to the similar course in pneumococcic infection of the pleura.

DR. GEORGE W. WEBSTER said that he was called to see a physician who was very ill and thought he was going to have pneumonia. He had a temperature of 103; but there were no physical signs of consolidation in the lung. The only signs were that the post-nasal space was much inflamed, beefy red, and angry-looking in color, the inflammation extending down along one side of the throat and involving a portion of the soft palate. The patient complained of intense pain in the post-nasal space. There was no membrane present. The post-nasal space was carefully swabbed out, and the material from the swabbing was sent to different laboratories for a report. He suspected the possibility of diphtheria. Both laboratories reported to him the following day almost a pure culture of the pneumococcus. There was a distinct crisis on the sixth or seventh day, and from that time on recovery was uneventful.

DR. EDWARD F. WELLS expressed the opinion that what might be called the less severe or minor cases had probably been observed in a larger proportion of instances than the reports in current literature and text-books would lead the profession to suspect. His own experience was limited to two cases. One was observed about twenty years ago, before bacteriologic examinations were made. The case was that of a child, 6 years of age, who had a sharp pneumonia followed by a left-sided empyema, which was opened, and followed subsequently by arthritis involving the left ankle joint. The inflammation ran an acute course; suppuration ensued; fluctuation was marked, and the joint was opened in two places, the front and rear, and through drainage instituted. The discharge was a thick creamy pus. His impression at the time was that the joint was completely disorganized, and that what he was doing was probably useless, and that amputation would be necessary later. However, it was thoroughly washed out, and within a week's time the purulent character of the discharge had given place to a serous discharge. The drain was removed and in a short time the openings healed, the patient recovered with good motion of the joint.

The second case occurred some three or four years ago; the sterno-clavicular joint was involved, symptoms appearing two or three days after crisis, which occurred at about the end of a week of the pneumonia, involving the lower lobe of the left lung. The left sterno-clavicular articulation was inflamed acutely; fluctuation developed within 48 hours, and a small opening was made. A thick creamy pus was discharged, smears from which showed the diplococcus of pneumonia. The sac was washed out with sterilized water; a thin serum exuded on two or three occasions; when the dressings were removed, no further trouble ensued, and healing occurred promptly. He was under the impression that it was a more frequent complication than Dr. Herriek thought.

DR. ROBERT B. PREBLE said it would seem that the occurrence of these complications must be much more common than the statistics would seem to indicate, when one considered that a dozen or more cases could be reported by so small an audience. He drew attention to some other arthritic manifestations which were seen with pneumonia and which were not due to infection. Those which he had seen had been of two sorts, namely, those which preceded the pneumonia, and those which followed it. He saw last winter a man between 50 and 60 years of age who, about forty-eight hours before he saw him, was seized with what was called acute articular rheumatism by the attending physician. This physician detected dulness in the chest, which he interpreted as pericarditis with effusion. When Dr. Preble saw the man he was able to demonstrate that the area in the chest was not due to pericarditis, but to consolidation of the left upper lobe. The joint manifestations sank into insignificance. The patient went through an ordinary course of severe pneumonia. Recently he had seen another case of the

same sort, where a patient entered the hospital, came to the examining room, and a diagnosis of acute articular rheumatism had been made; but there were arthritic manifestations preceding those of pneumonia.

A second class of cases were post-pneumonia arthralgias. Patient would usually have some pain in joints, but without any demonstrable changes, and the pain continued for a short time and then disappeared. His idea had been that these manifestations were perhaps toxic rather than actual infective manifestations. Of course, it was possible they were infections in which the effusion was so small as to escape detection, and in some of these cases the process terminated favorably in a short time.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### Scarlet Fever.

The following outline of treatment to be employed in scarlet fever is recommended by W. W. Robertson, of McComb, Miss., in an article in *Pediatrics*. The patient should be properly isolated in a room spare of furniture such as carpets, rugs, etc. The fever must be combated when it reaches 103, by cool sponging, and when higher, with meningeal symptoms, the cold pack or tubbing may be employed. The bath should not be as cold as that employed in typhoid fever. The warm bath at 90 allays the irritation of the skin also, but injections of sweet oil or cold cream serve as well to allay the irritation and are necessary as soon as desquamation takes place, to prevent the scales from spreading contagion. An ice cap to the head is very important, especially if the temperature is high and there are cerebral symptoms present. Cool applications are positively non-indicated in the absence of fever, as they increase the tendency to otitis media and to renal complications. Elimination must be promoted by the kidneys and bowels. The official solution of potassium citrate or ammonium acetate combined with spirits of nitrous ether with a little flavoring syrup is useful. The constipation must be relieved.

If local measures to the throat are necessary, peroxid of hydrogen (1 to 3), or a solution of bichlorid of mercury (1 to 5000), or a carbolic spray (1 to 50 or 60) may be employed. The peroxid of hydrogen solution is preferred. He favors the application of a bandage to the throat, with pockets opposite the tonsils, into which pieces of ice are placed and the whole covered with a towel; or a small India-rubber ice-bag may be used similarly. The proper treatment of the throat saves the ear; but should the middle ear become involved, the membrana tympani must be watched; if its tension is extreme perforation should be performed, even more than once if necessary. The prophylaxis against nephritis should be most careful, and draughts of air guarded against.

### Enuresis in Children.

In an article in *Pediatrics*, it is stated that the average general practitioner who gives to every patient a few drops of tinctura belladonnæ for the relief of enuresis, as a rule, derives poor results. The most important thing in the treatment of enuresis is the improvement in the child's general condition by exercise, diet and, above all, daily cold bathing. This alone will sometimes produce a cure. Such children should not drink any water after supper and but one glass of water at supper. If phimosis, balanitis or preputial adhesions exist, they should be treated, but where circumcision is not indicated, enuresis will persist after the operation. The drug most frequently employed is atropin, often better combined with strychnin, in increasing doses until symptoms of poisoning appear; then the dose should be gradually decreased, and increased again if enuresis recurs. This method of treatment

rarely fails. Where the urine is highly acid, salol and boric acid have rapidly produced recovery. The child must be trained through the day to control the sphincter of the bladder; this must not be forgotten. Punishment is useless; while very neurotic children will need rest and absolute freedom from all excitement.

#### The Drug Treatment of Neurasthenia.

Dr. Daniel R. Brower, in an article in the *Internat. Med. Mag.*, states that neurasthenia is an autotoxie and exhaustion neurosis, and therefore requires, first eliminants. To promote elimination by the bowel he recommends the following:

|                         |          |      |
|-------------------------|----------|------|
| R. Extracti aloes ..... | gr. viii | 52   |
| Extracti taraxiei ..... | gr. xvi  | 1 06 |
| Pulv. ipecacuanhæ ..... | gr. i    | 06   |
| Ext. hyoscyami .....    | gr. viii | 52   |

M. Ft. capsule No. viii. Sig.: One at bedtime for the bowels.

He states that the dose of each of the foregoing ingredients should be regulated to suit the patient. According to his experience this pill acts as a stomachic tonic, a mild diuretic and as a laxative. In addition to this pill he recommends colonic flushings once or twice a week, using the high normal saline injection.

To increase the renal elimination the following is advised by him:

|                             |     |        |
|-----------------------------|-----|--------|
| R. Potassii citratis .....  | 3v  | 18 75  |
| Ext. adonis vern. flu. .... | 3ss | 1 90   |
| Aq. aurantii .....          | 3iv | 124 00 |

M. Sig.: One teaspoonful before each meal in hot water.

The exhaustion part of neurasthenia must be treated with alteratives and tonics. The following alterative is considered by him to be the most efficient:

|                                 |        |      |
|---------------------------------|--------|------|
| R. Auri et sodii chloridi ..... | gr. ii | 13   |
| Pulv. resinae guaiaci .....     | gr. C. | 6 50 |

M. Ft. capsule No. xx. Sig.: One capsule one-half hour before each meal.

He examines upon repeated examinations of the blood in every case in order that the iron may be intelligently administered or withheld. He regards Bland's mass freshly prepared as the best form, prescribed as follows:

|                       |         |      |
|-----------------------|---------|------|
| R. Ferri sulph. ....  | gr. xl  | 2 66 |
| Sodii carb. ....      | gr. xl  | 2 66 |
| Ext. nucis vom. ....  | gr. iii | 18   |
| Sodii arsenatis ..... | gr. i   | 06   |

M. Ft. cap. No. xx. Sig.: One capsule after each meal.

The author believes that nux vomica and its alkaloids do harm when given in large doses in the treatment of neurasthenia. When the hemoglobin has increased so that the administration of iron is no longer necessary, he recommends the use of phosphorus in the form of zinc phosphidum gr. 1/10 (.006), or calcii glycerophosphas gr. v (30), or syrupus hypophosphiti U. S. P. 3i (3.75), to be given after meals.

For the nervous system as a sedative, the following is given:

|                                 |      |       |
|---------------------------------|------|-------|
| R. Sodii bromidi .....          | 3vi  | 22 50 |
| Essentia pepsini q. s. ad. .... | 3iii | 93    |

M. Sig.: One teaspoonful in water as necessary.

He advises against the continuous use of nerve sedatives on account of the danger of inducing the drug habit. The insomnia, which is a stubborn symptom, should be combated without the use of drugs if possible; otherwise, the following combination containing chloral and sodium bromid may be used:

|                             |     |       |
|-----------------------------|-----|-------|
| R. Chloralis hydratis ..... | 3iv | 15 00 |
| Sodii bromidi .....         | 3iv | 15    |
| Ext. glycyrrhizæ flu. ....  | 3ii | 7 50  |
| Aque q. s. ad. ....         | 3ii | 62    |

M. Sig.: One teaspoonful in water at bedtime and repeat in one hour if necessary.

#### Acute Bright's Disease.

Acute Bright's disease is recognized and encountered by the general practitioner at the present time more often than formerly. It is a severe condition which may arise after a "cold," scarlet fever and in a milder form following la grippe and severe toxemia arising from auto-intoxication. According

to *Merck's Archives*, if these acute attacks are properly treated the mortality should be nil and should never be followed by chronic nephritis. In the management of these cases the temperature of the room should be uniform, ranging between 74 and 78 F. It should be ventilated and great care must be taken to avoid draughts or the chilling of the patient. The diet should be milk in some form and plenty of water. The renal congestion must be relieved and elimination by the kidneys increased. If this can not be accomplished other channels must be induced to do greater work. Counter-irritation over the kidneys may be obtained by the application of the following ointment:

|                             |        |      |
|-----------------------------|--------|------|
| R. Chloralis hydratis ..... | 3i     | 3 75 |
| Spts. Camphoræ .....        | 3i     | 3 75 |
| Olei terebinthinæ .....     | 3ii    | 7 50 |
| Olei sinapis vol. ....      | gtt. x | 66   |
| Pulv. capsiei .....         | 3ii    | 7 50 |
| Petrolati .....             | 3ii    | 60   |

M. Sig.: Apply with friction over the region of the kidneys every three to six hours; or as a poultice for the same purpose:

|   |      |     |
|---|------|-----|
| R. Lini contusi (ground flaxseed) ..... | 3xvi | 480 |
| Pulv. sinapis migræ .....               | 3ii  | 60  |
| Pulv. digitalis (leaves) .....          | 3iv  | 120 |
| Pulv. jaborandi (leaves) .....          | 3iv  | 120 |

M. Ft. poultice. Sig.: Apply locally over the kidneys.

Internally as a diuretic and diaphoretic the following:

|                             |        |      |
|-----------------------------|--------|------|
| R. Infusi digitalis .....   | 3iii   | 93   |
| Pot. bitartratis .....      | 3i     | 31   |
| Spts. nitrosi etheris ..... | 3i     | 31   |
| Spts. glonoini .....        | m. xvi | 1 00 |
| Sol. ammon. acet. ....      | 3iii   | 93   |
| Syr. idæi q. s. ad. ....    | 3viii  | 248  |

M. Sig.: Shake; one tablespoonful every two to four hours, according to indications.

As a diuretic and cathartic:

|                                  |       |    |
|----------------------------------|-------|----|
| R. Hydrarg. chloridi mitis ..... | gr. i | 06 |
| Pulv. scillæ .....               | gr. i | 06 |
| Pulv. digitalis .....            | gr. i | 06 |

M. Ft. pil. No. i. Sig.: One such pill three times a day.

This pill may be followed after a due length of time, by a saline cathartic such as magnesium sulphate.

### Medicolegal.

**Difference in Malpractice Case on Second Trial.**—The first question to confront the Supreme Court of Wisconsin, on the second appearance before it of the malpractice case of Kiekhoefer vs. Hidershede, was whether or not, upon the second trial, there was new evidence with reference to the treatment of the wrist of the party suing, so as to take the case out of the rule that the decision on the former appeal was *res adjudicata*, or conclusive, at all future stages of the case. Upon the former trial it was testified by the physician sued and another one that the fragments of the broken radius were brought into apposition, and so retained until they healed, save for a very slight displacement whereby the lower fragment had a dorsal protrusion of about one-eighth of an inch above the upper fragment, and an inward projection of about one-sixteenth of an inch toward the ulna. This testimony was then undisputed, the only other evidence on the subject being that of a third physician that he found "some displacement," and that he also found something of the malformation of the wrist characteristic of the Colles fracture, known as the "silver-fork" or "bayonet" deformity. It was also proved, practically without dispute, that it was consistent with due skill and care to allow the fracture to heal with no more displacement than this, rather than rebreak the bones to place them in perfect apposition. But, upon the second trial, the third physician referred to testified that, in his opinion, formed at the time of examination, the backward displacement of the lower fragment was a half an inch, so that the ends of the fragments were practically not in apposition at all, merely the lower or front edge of one fragment touching or overriding the upper or backward edge of the other fragment; and, that he was still of that opinion, although the

bones were so grown into a mass of callus that it was impossible to distinguish bones from callus, or to tell their exact position. He also testified, with enough definiteness to distinguish it from his former testimony, that the silver-fork deformity of the wrist was "marked," and that it could be due only to displacement of the bones, while a new witness, called for the defense, testified that from such displacement as that described by the physician sued the deformity could not be "pronounced." Under these circumstances, in affirming a judgment for \$1200 damages, the Supreme Court holds that this evidence, produced for the first time on the second trial, of an amount of displacement greater than that testified to by the physician sued, albeit only an opinion, was sufficient to carry to the jury the question, not in dispute upon the former trial, whether his statement of the amount of displacement which he allowed to heal up was true, and that, therefore, the court was not precluded by its former decision from considering whether there was presented a jury issue as to his negligence, in treating the fracture, nor as to the effect of such negligence in producing the whole or any part of the ultimate injury to the patient's wrist.

**Insufficient Allegation of Qualification.**—The Supreme Court of Kansas holds, in the case of Westbrook vs. Nelson, that an allegation in a bill of particulars filed for the purpose of recovering an account for medical and surgical services performed, which alleges "that plaintiff is a physician and surgeon duly entitled to practice medicine and surgery under the laws of the state of Kansas," is not a sufficient allegation of qualification and authority under the law to engage in the practice and recover compensation for services performed months before the commencement of the action in which such pleading is filed. For this reason, the court, in this case, reverses a judgment obtained by a physician, holding that error was committed in overruling an objection to the introduction of evidence under the pleadings. It says that it was essential to a recovery by the physician that at the time of performing the services he possessed the requisite qualifications prescribed by statute. The act expressly so declares. That such qualification may be shown, it must be pleaded. Had the pleadings alleged qualification and authority to engage in the practice of medicine and surgery at the time of performance of the services, and no issue thereon had been joined by proper denial, the allegation of authority would have required no evidence in its support. The fact of proper authority and qualification under the law would have stood admitted. In the light of the authorities, it must be held the allegation of qualification at the time of filing the pleading found in the pleading in this case, was not a sufficient allegation of authority to admit of proof of proper qualification to follow the profession at the time the services were alleged to have been performed, months prior to the filing of such pleading.

**Agency of Medical Examiner.**—The Court of Appeals of New York says that the decision of the case of Sternaman vs. the Metropolitan Life Insurance Company turned substantially upon the following question: When an applicant for life insurance makes truthful answers to all questions asked by the medical examiner, who fails to record them as given, and omits an important part, stating that it is unimportant, can the beneficiary show the answers actually given, in order to defeat a forfeiture claimed by the insurer on account of the falsity of the answers as recorded, even if it was agreed in the application that the medical examiner, employed and paid by the insurer only, should not be its agent, but solely the agent of the insured? This question the court answers in the affirmative. It thinks that it is well established by the weight of authority in that state that the medical examiner is the agent of the insurer in making the examination, taking down the answers, and reporting them to the company; that his knowledge thus acquired, his interpretation of the answers given, and his errors in recording them, are the knowledge, interpretation, and errors of the company itself, which is precluded from taking advantage of what it thus knew and what it had thus done when it issued the policy and accepted the premiums. Referring to this case, it says that the insured had nothing to do with the medical

examiner, except to submit to an examination by him, as the expert of the company, and to answer the questions asked by him in behalf of the company. This he was forced to do in order to procure insurance; for the company required him to undergo a medical examination by an examiner selected and instructed by it, before it would act upon his application for a policy. He could neither refuse to be examined, nor select the examiner, and he was not responsible if the latter was negligent or unfit for the duty assigned to him. He could not direct or control him, but the company could and did; for it required him to make the examination, fill out a blank furnished for his use, and report the facts with his opinion. The insured made no contract with the examiner, and was under no obligation to pay him for his services. The company, however, made a contract with him to do certain work for it, and agreed to pay him for the work when done. As between the examiner and the insured, the relation of principal and agent did not exist, while, as between the examiner and the company, that relation did exist by operation of law. Under the circumstances, an agreement that the physician was the agent of the insured was like an agreement that the company or its president was his agent. It was in contradiction of every act of the parties and of every fact known to either. The law, when applied to the facts, made the physician the agent of the company, and not of the insured; and it could not be held that, as the insured agreed that the physician was his agent, he became such in spite of the law and the facts. While the contract between the physician and the company was still in existence, the latter agreed with a third party only that that contract did not in fact exist between the two parties who made it, but did exist between two parties who did not make it. This was not possible by any form of words, any more than to make black white, or truth falsehood.

1. **Methylene Blue as a Sedative.**—Following the suggestions of Bodoni, who found that this drug seemed to have a marked sedative effect in nephritis, Hughes and Lovelace have experimented with it in over twenty cases of wild excitement and in only six was there failure to calm. The other patients were relieved without experiencing dulness or hebetude. The effect was noticed three to four hours after the dose was given and lasted from fifteen to twenty hours. No sleep was produced in the day time, but the patients slept well at night and no depression resulted at any time, with the exception of one case, in which it was mild. There were no derangements of the gastro-intestinal canal.

2. **Tuberculosis.**—Flick holds that the primary production of tuberculous germs is not directly in the lungs, but that: 1. The seed supply for new implantations of tuberculosis is derived, almost entirely, from human sources, especially the sputum of consumptives. 2. Seed supply for new implantations of tuberculosis can be derived from animal sources. 3. The tubercle bacillus enters a host through the lymphatic system in the alimentary canal, the respiratory tract and the skin. 4. The forces which convey the tubercle bacillus to its place of destination within a host are the lymph current and the blood current. 5. The place of deposit is no indication of the port of entry of the tubercle bacillus except when deposit has taken place in the bronchial lymphatic glands or in the mesenteric lymphatic glands. 6. Interference with the circulation of a part, whether by traumatism, inflammation or vasomotor disturbance, prepares the part for tubercular deposit. 7. Germination and colonization do not always follow tubercular deposit.

3. **Vaccination.**—Wood believes the method of scarifying for vaccination is bad. The proper way is to make one single scratch with a sterilized cancri needle, which can be readily sterilized by passing through a flame. The best dressing is a small piece of dry sterile gauze fastened by means of a plain bandage, pinned to the undershirt from the outside with a safety pin, or fastened to the arm by a piece of non-irritating adhesive plaster. This ensures good ventilation, absorbs the secretion and keeps out foreign substances. The arm should be cleansed with alcohol or with soap and boiled water and rubbed a little to bring the blood to the surface. The arm is scratched just once, not to draw the blood, but simply to penetrate the cuticle and the virus is then applied and rubbed in well with the ivory point.

4. **Finger Amputations.**—The methods of performing finger amputations are noticed by Deaver, who describes the method as follows: "When amputating near the distal joint the operator should save, if possible, the base of the distal phalanx as the long flexor and extensor tendons are attached at this joint and their function is thereby preserved. In amputating at any point above the distal joint, the cut ends of the tendons should be stitched either to the periosteum or to the flap, thus preserving their function. Semm says, in amputating a finger below its base, the extensor tendon should be sutured to the flexor tendon over the articular end or sawn surface of the bone. This will prevent undue retraction of the flap and furnish the cut ends of the tendons with a permanent point of anchorage. The teaching has been to amputate the middle and ring fingers at the metacarpophalangeal articulation. The surgeon should save as much of these two fingers as possible, for by the above method of fastening the tendons the stumps of these fingers become useful; the inter-ossei muscles, too, are supposed to play a part in flexing these fingers. It is advisable to saw through the bone, instead of cutting with the forceps, as the latter procedure is liable to splinter the bone. Before

sawing through the bone the periosteum should be deflected in the form of a cuff; after the bone is divided the periosteum should be pulled down and sutured with fine catgut over the end of the bone. It is unnecessary to round off the edges of the bone as these are readily absorbed. The cut nerves should be drawn down as far as possible and cut high; this will prevent the nerve from being caught in the scar and causing the condition known as painful stump. The arteries should be left as long as possible and by twisting them sufficiently ligation may not be necessary. If an elastic constrictor has been used, this should be removed suddenly, the old notion that the elastic tube should be removed slowly, thus being apt to cause hemorrhage, is erroneous. Before closing the wound it should be thoroughly washed with hot saline solution and should be perfectly dry. Drainage should usually be introduced either in the shape of a small tube or a strip of gauze. The cut edges should be accurately approximated and stitched with silkworm gut; use as few stitches as are necessary to bring the flaps into apposition. By inserting too many stitches the part becomes constricted, the blood supply shut off, drainage is prevented and the tension causes pain. In the perfect stump the flaps are freely movable over the end of the bone. Always immobilize the stump by placing the hand on a splint; this is very essential to secure absolute rest. If for any reason the stump should become infected, remove the stitches and make free longitudinal incisions into the stump, if there is any swelling. In disarticulating the fingers at the metacarpophalangeal joint, the lateral flap method is perhaps the best. This is done by making two separate incisions, beginning about three-quarters of an inch above the head of the metacarpal bone and extending around to meet on the palmar aspect of the base of the first phalanx. In case it is necessary to remove the metacarpal bone, this can be done by extending the incision just described, up the dorsum of the metacarpal to the carpometacarpal joint. The operator should make the knife hug the bone as closely as possible to avoid cutting the palmar arch or other structures in the palm. The surgeon should be extremely conservative in operating on the thumb, as this is the most important finger on the hand. It is advisable to try excision on the bones of the thumb before resorting to amputation."

6. **Cystic Kidney.**—Osler reports two cases which illustrate very well the general features of cystic kidney. In one of these the diagnosis was easily made. He gives the following characteristic symptoms which were present in these cases: 1. Bilateral tumors were present in the flanks. The polycystic kidney is rarely unilateral. Of the 88 cases collected by Ritchie both kidneys were involved in all but two. In the 62 cases tabulated by Lejars only one was unilateral. The tumors are often unequal in size as in the two cases reported here. There was no difficulty in recognizing that the tumors were renal. The situation and mobility should at once raise suspicion. 2. The cardio-vascular changes of interstitial nephritis are very pronounced in one of these cases, there being dislocation of the apex beat to the left and accentuation of the aortic second sound. 3. The condition of urine was that of advanced interstitial nephritis, low specific gravity, trace of albumin, few red blood corpuscles and scanty tube casts. An interesting feature in the second case was the presence of cholesterol crystals. 4. Hematuria occurred in the second case in attacks for more than one year. This symptom may be associated with much pain. The reason Osler suggests for the failure to diagnose so many cases is that cardiac insufficiency and dyspnea mislead the physician and the kidney condition is neglected.

7. **Malarial Skin Disorders.**—Riesman reports a case and concludes his article with the following: 1. Skin eruptions are not rare in malarial infection. 2. The most frequent are herpes and urticaria. 3. Neither of these presents any specific characters. 4. Both may occur in any stage of the malarial paroxysm, although urticaria is most frequent in the febrile, and herpes in the sweating stage. 5. In obscure cases, herpes and urticaria, especially the former, may have considerable diagnostic value. 6. Three types of urticaria are recognizable: That accompanying the paroxysm, usually the febrile stage; that taking the place of the chill; and that substituting the entire

paroxysm. 7. In their appearances, these three do not differ among themselves, nor from urticaria due to other causes. 8. In cases of urticaria of obscure etiology, the blood should be examined for plasmodia. Whether found or not, quinin is worthy of a trial.

8. **Laparotomy for Carcinoma.**—Corson reports a case of general carcinoma of the breast involving the skin of the entire chest, diagnosed microscopically. Laparotomy was performed and marked improvement followed. He suggests that the value of the Beatson method is not from the removal of the ovaries, but simply from opening the abdomen. He considers that the retrograde processes in his patient are probably greater than if he had removed the tubes and ovaries—as he started out to do—and disturbed the peritoneum more. Much injury to the peritoneum would probably divert the healing energy to this part and the benefit to the carcinoma would be less. The rapid relief of infiltrated tissues at the end of 48 hours points to the lymphatics, he says, as channels of escape. He asks: Does not the opening of the peritoneum, the great lymph sac of the body, and the introduction of air stimulate the great lymphatics of the abdomen and cause a current that carries everything along with it, exciting a similar current in the lymph of the tumor?

9. **Gastric Chemistry.**—The methods before described by Knapp have been recently tested, especially the easy method of detecting succinic acid, which, he says, is evidence of the presence of mold if it is of anything. He reviews his tests and confirmatory experiments saying: The general deduction to be made from these experiments, as bearing upon the chemic analysis of the chyme, is: Whenever the ether extract of the chyme shows a ring, yellow or reddish brown, organic acids are present. Lactic acid must never be assumed unless the chyme still gives a sulphur-yellow ring after the acidity of the chyme has been brought down to 20 by dilution with distilled water. When testing for lactic acid no alcohol must be added, as this in itself gives a yellow ring—this would, however, require a very strong or a large quantity of alcohol. As a test for free HCl to be used for volumetric analysis he has found the best to be a saturated solution of tropeolin OO, which is sufficient for chyme analysis. His method of procedure is as follows: To 5 c.c. of the filtered chyme, in a beaker, are added two drops of the saturated alcoholic solution of tropeolin OO, this is titrated in the ordinary way with the decinormal solution of caustic soda until the purplish-red color has entirely disappeared and the contents in the beaker have the appearance of an ordinary tea infusion, somewhat of an amber color. This is the end reaction for tropeolin. Now two drops are added of a .5 per cent. alcoholic solution of dimethylamidoazobenzol which turns the contents in the beaker red, in the presence of organic acids. The titration is further continued until the chyme turns a lemon color. Now two drops of a 1 per cent. alcoholic phenolphthalein solution are added and the titration resumed until the beaker contents turn red. The buret reading at the end of each titration is noted and the calculations are made accordingly. He claims this method has a great advantage over all methods in the short time required and its being an easy way of qualitative and quantitative estimation of organic acid. The first titration gives the quantity of free HCl, the second the possible quantity of organic acids. He has corroborated his claims for this test by different methods and holds that it is an excellent indicator for free HCl estimation not inferior to the more expensive Ginzburg reagent. The reagent for acid phosphates used by him is ferrieyanid obtained by ferric chlorid and ammonium sulfoeyanid. Whenever the acid phosphates are present in chyme they react on the ferrieyanid, and when the latter does not react there are no acid phosphates.

12. **Yellow Fever.**—Carter holds that yellow fever may be carried by vessels—only, however, by the carrying of infection-bearing mosquitoes. He sums up as follows: 1. Vessels aboard which yellow fever had been contracted, i. e., vessels infected with yellow fever, have not been rare, at least at southern quarantine stations. 2. Such vessels are much rarer since 1893 and are not very common now. 3. The diminution in the number of infected vessels reaching United States ports is due mainly

to the sanitary measures for avoiding exposure to infection in the foreign port and to the substitution of steam for sailing vessels. To some degree the falling off of the vessels from Brazilian ports is also a factor. 4. A case of yellow fever developing aboard a vessel plying between southern ports of the United States and the tropics will probably infect the vessel, so that other cases can, if time be given, be contracted aboard her. 5. Such vessels, however, if short-trip vessels, not more than ten or twelve days *en route* after the occurrence of the case of yellow fever, will in general be disinfected at southern quarantine stations before any other cases have been contracted abroad, although harboring infected mosquitoes. 6. That a case of yellow fever so occurring aboard a vessel from a northern port of the United States would be able to infect her or not according to whether she had acquired the mosquito *stegomyia fasciata* in the tropical port. 7. It is, in general, then, necessary to disinfect all vessels running between southern ports of the United States and tropical ports if a case of yellow fever occurs aboard, no matter where it be contracted; while vessels running between northern ports and the tropics may, through precautions in tropical harbors, have no *stegomyia* aboard, and are thus not infectable by cases of yellow fever occurring aboard. 8. Some vessels giving no history of yellow fever in port, *en route*, or on arrival—even when many days *en route*—are nevertheless infected and communicate the yellow fever to those who go aboard.

**14. Gauze Packing in Appendicitis.**—The dangers and inconveniences of gauze packing in appendicitis are described by Morris, who holds that it causes excessive exudation of reparative lymph which may result in peritoneal adhesions and may also cause ileus and bowel obstruction by simple mechanical pressure. Its use usually leaves a weak place in the abdominal wall and favors post-operative hernia. The worst feature of its use is that it acts as a foreign body, depressing the patient's general resistance and prolongs, if it does not cause, a condition of surgical shock. He does not mean to advise that it should be given up at once, but one should work towards the point of giving up gauze drainage as rapidly as experience shows it to be safe.

**16. Chronic Rheumatism.**—The theory of Merrins is that so-called chronic rheumatism is due to original infection and the term ought to be applied only to those rare cases where there is a clear or unbroken connection with the attack of acute rheumatic fever.

**21. Spondylitis Deformans.**—This condition is discussed at length in this second paper, the disease having been described in a former one presented in May, 1899, to the American Orthopedic Association. In this article he goes further into the symptoms and treatment and describes and illustrates cases. The prognosis is considered and is, on the whole, rather favorable under treatment if taken early. In a certain number of cases the disease is so mild that the muscles alone are able to protect the part, but without treatment in the majority of cases the disorder gradually extends under the continued irritation from motion until the patient is obliged to give up and go to bed. Under the imperfect rest, which this represents, the process gradually but slowly quiets down and the patient is about again, suffering only from a stiffness in the region involved. The possibility of relapse from the weak point left should be considered in the prognosis and the effect on the lungs due to the limitation of respiratory movements from ankylosis. Pulmonary tuberculosis has been seen to develop after the thoracic movement has been thus restricted.

**22. Privileged Medical Communications.**—Cheever's article is a reply to Nichols' paper published in the same journal of January 2, which defended the existing laws. Cheever holds that the physician's position before the courts is a false one in proportion to his sense of honor. He proposes the following modifications of the Massachusetts statute: It shall be considered unprofessional and improper for a physician to divulge anything confided to him by a patient, unless: 1, with the patient's consent; 2, to defend himself when accused; 3, to expose crime; 4, in all other cases such professional confi-

dences shall be classed as "privileged communications." It shall be a question of honor whether the physician shall ever feel it his duty to repeat such a "privileged communication"; if he conscientiously declines, he shall be protected; if he conscientiously testifies, it shall be before the judge or referee only, in private; and no such revelation shall be published.

**23. Extra-Uterine Pregnancy.**—The cases reported by Reynolds illustrate the difficulties in diagnosis. In one case, while the patient suspected her condition, the symptoms were inconclusive; in another there were no signs of pregnancy whatever and no pain, but there was rectal tension accompanied by diarrhea due to mechanical irritation and a tumor was diagnosed. An extra-uterine pregnancy in the Douglas fossa was found. In the third case there were no symptoms of pregnancy except menstrual irregularity and sharp abdominal pain preceded by cramps and a gradual development of tumor. The condition proved to be an acute hydrosalpinx alongside of a small ovarian cyst. The other cases were similar, as regards the deceptiveness of symptoms described.

**29. Epignathus.**—Jewett reports a case of this rare anomaly of a twin monstrosity in which the parasite was united to the supra-maxillary bone. He describes the case and discusses the origin, supporting the belief of Bandler that the dermoid cyst and teratoma are invariably due to displaced ectoderm and mesoderm cells.

**31. Aseptic Surgery.**—The distinction between aseptic and antiseptic surgery is pointed out by McBurney, who shows the uselessness of an attempt to destroy all germs and the irritating effects of strong antiseptics which would alone be effective. He advocates the use of the rubber glove as the only method of sterilizing the hand, and claims that the alleged disadvantages from loss of the tactile sense, etc., are not realized. It is of great importance also to have a first-class assistant; frequent changing of assistants is deprecated. The knives should be sharp so that incisions will be clean-cut; all so-called blunt dissections should be avoided as they affect the vitality of the parts. The more perfectly nutrition is furnished through uninjured blood vessels to the tissues involved in a wound the more certainly will scattered bacteria be destroyed. Hemorrhage should be checked as early as possible to save the blood and also to prevent the formation of small blood clots which may be left and produce culture facilities for germ growth. Antiseptics must be regarded as harmful foreign bodies and totally unsuited to the interior of any wound. The ligature should be of fine material so as to leave only small knots and should strangle as small a bit of tissue only as is essential; all ligatures and buried sutures should be of absorbable material, like catgut. Hemostasis should be as complete as possible. Complete aseptic work demands that the wound should be treated with the utmost delicacy in this respect and the avoidance of over-injury of tissue as far as possible. He maintains that it is frequently possible by exercising sufficient care to obtain clean aseptic healing in septic wounds, and as an instance of this notices his success in the treatment of abscesses. It is a good idea to give sufficient volume of blood to the tissues, therefore he advocates the rectal injection of hot normal salt solution. Wounds should be immobilized to prevent hematoma and dressings should be large for protection and soft for comfort.

**32. Tuberculous Joint Disease.**—Wilson describes the symptoms and occurrence of tubercular joint disease, its insidious origin, its special signs such as muscular rigidity, the uselessness and danger of anesthetizing in examining a patient for such a condition as it removes the one symptom which is constant and unvarying in incipency, namely, muscular rigidity. It has become a well-known fact that, even when extensive invasion has occurred, absorption and resolution may be secured, showing the controllability of the condition. The principle of rational treatment would appear to him to be securing ankylosis rather than to attempt to avoid its occurrence.

**34. Congenital Syphilis.**—Malnutrition in children is attributed by Kerley to syphilis in many cases where other symp-

toms are lacking. In cases where parents are of average health and strength with negative family history and the child or children show low vitality, indifferent food capacity and poor appetite, he adds bichlorid of mercury or iodid of potash to the treatment regardless of the standing of the patient and is usually gratified, but never surprised, by the satisfactory outcome. He has learned to look with suspicion upon puny delicate children of parents with average good health, when there is no discoverable reason for the mal-nutrition and resisting well-directed hygienic and supporting measures.

**36. Antiphthisis Serum T. R.**—Experience with this remedy at Fort Bayard, N. M., is reported by Bullock. The results apparently were comparatively negative and about comparable to those in cases treated without it. He believes the favorable results of the agent as generally interpreted occur naturally as the result of proper hygienic surroundings in a large proportion of tuberculous cases rather than to the effect of the serum. It is very easy to attribute to one drug used exclusively what occurs naturally under proper environment.

**37. Synovitis of the Knee.**—The condition here described by Thomas is usually met with in males and often taken as a sprain. It is characterized by pain on moving, tenderness, enlargement of the joint without much loss of motility but with pain on flexion of the joint. In treatment by immobilization in the well-marked cases the average duration is five weeks. He describes the distinction from tubercular disease, acute rheumatism, gonorrhea, syphilitic affections and hematoma. The symptoms are less serious than any of these and the remedial measures usually mechanical. The leg should be put in a position of full extension to relieve strain and the rest method need apply only to flexion and rotation. The joint must be immobilized so long as there is any excess of fluid or a point of distinct tenderness, as recurrence may then follow movement of the joint. Massage may be useful if employed the first twenty-four hours after the injury and also in the later stages, when tight strapping and counter-irritation are also of real service.

**38. Skin Diseases.**—There is no specific medication for skin diseases, with the exception of the syphilids and even syphilitics are sometimes benefited by omitting specific medication and treating the symptoms. Cutaneous affections should be cured as speedily as possible. The diet and hygiene are especially insisted upon. A certain proportion of cases are self-limited, running a definite course, requiring little in the way of treatment but relief of the depressing symptoms. There are others that are benign in character but incurable, and still others that are fatal in spite of all medication. Of course, malignant disease will have to come under the care of the surgeon. The class of cases here considered are those which require active and thorough medication. Carrier thinks the popular notion that arsenic is almost a specific in skin diseases has done an immense amount of harm. There are only a few cutaneous disorders where it can be used with a fair prospect of doing good. It had better not be used at all than used indiscriminately. In acute inflammations it should never be given. It is in chronic affections characterized by exfoliation that it is useful. In psoriasis, squamous eczema, lichen planus and pemphigus it may be used, but even in these cases it is well to try other remedies first. Alkalies are very valuable in cutaneous diseases, indicated whenever there is an active congestion. Antimony deserves more consideration as a remedy than it is receiving. Carrier knows of no remedy that gives as good results in dermatoses occurring in robust individuals with florid complexions who are hearty meat eaters. It relieves the congested state, assisting in clearing out the waste distribution through the alimentary canal and the kidneys. Mercury is very useful in affections characterized by induration—such as old cases of eczema—aside from its specific action in syphilis. It is of great value in small doses in eczema of children, especially in the pustular forms, and wherever there is defective elimination. The salicylates are useful in congested conditions and those of rheumatic or gouty character. In urticaria not due to indigestion they are almost a specific. Ichthyol is of value in the various vasomotor disturbances and in acne in plethoric

cases, also in urticaria and in rosacea. Calcium sulphid seems sometimes to interfere with pus formation; again, it hastens the process in sluggish cases. He has had better results from small doses often repeated than from the large ones. The iodids are useful as eliminants, but untoward effects sometimes follow their use and should be watched for.

**42. Mechanical Asepsis.**—The method advocated by Ward is the filtration of air passing to the wound through dry absorbent cotton. He maintains that this is the best and most satisfactory method; absorbent cotton absolutely solves the whole problem, for example, in the management of blisters.

**43. Acute Endocarditis.**—Herrick reviews the general subject of endocarditis and its causes, which may be multiple from a bacteriologic point of view, and be dependent upon any suppurative focus in other parts of the organism. He believes in the classification into the benign and malignant types, since we can not recognize any specific organism causing it, though the terms are loose in an anatomic and to a certain degree also in a clinical sense. The prognosis seems to be favorable in the benign form and there is evidence, not only clinical but anatomic, of the occasionally favorable outcome of the severe ulcerative type. He goes at length into the subject of diagnosis, pointing out the two diseases which most successfully mimic ulcerative endocarditis, malaria and typhoid, especially the latter, and the striking resemblance to tuberculosis. With the emaciation, anemia, slight cough, rapid pulse, dyspnea, slight chills, sweats, irregular temperature and slight hemato-lysis, only a close physical examination with perhaps careful watching of the patient for a week or more will make the diagnosis certain, and repeated examination of the lungs, sputum, blood and heart will be required. The primary disease may overshadow the condition of the heart. This should also be borne in mind. The complicating lesions also are to be guarded against as possibly receiving too much emphasis in the clinical consideration. As non-malignant cases frequently recover spontaneously, he thinks, even in desperate cases, we should persist in our efforts, insist on rest of the body and heart, eliminate the primary focus of infection, treat untoward complications, aid elimination and strive in every possible way to overcome the existing septicemia and toxemia.

**44. Rectal Stricture in Women.**—Rothrock reports three cases in which rectal stricture seemed to be conditional on inflammatory pelvic disease. In one there was an exudate of almost stony hardness, fixing the uterus and adnexa, causing infiltration and exudate and producing rectal stricture. Colostomy was required to relieve the condition.

**45. Surgery of the Gall-Bladder.**—The conclusions of Ochsner's article are given as follows: "1. The diagnosis of diseases of the gall-bladder and of gallstones requires further study and observation. 2. The classical symptoms must be supplemented in order to be sufficient as a basis for diagnosis. 3. It is not wise to operate during the acute attack of cholecystitis. 4. Patients much reduced by long-continued suffering do not well bear prolonged operations upon the gall-bladder and ducts. 5. Robson's observation that patients with carcinoma of intra-abdominal organs do not bear gall-bladder operations well has been borne out by my experience. 6. If the operation can not be postponed in presence of extreme jaundice, it should be confined to simple drainage of the gall bladder."

**54. Hereditary Cerebral Ataxia.**—Patrick's article is an elaborate discussion of the literature and a report of cases. He doubts the propriety of considering this a distinct nosologic species and thinks for the present it would be wise to follow Sanger Brown's example and simply use the term hereditary ataxia. It seems reasonable to conclude that it is identical with Friedrich's disease, co-ordination and equilibration being only more affected.

56.—See abstract in *THE JOURNAL*, xxxvii, p. 1480.

59.—See abstract in *THE JOURNAL*, xxxvii, p. 852.

61.—*Ibid.*

66.—This article has appeared elsewhere. See *THE JOURNAL* of January 18, 19 and 20, p. 202.

**67. Provisions for the Insane.**—The first part of Peterson's paper is historical. He says at the present time Germany approaches nearer the ideal standard, which may be expressed as small hospitals for the acutely insane in cities and colonies for the chronic and mixed classes of insane in adjacent country. He notes the conditions of location, etc., for the colonies, and remarks that the first thing must be an administration building and a small hospital for the acutely insane, which will have to be treated here as well as in the cities. Afterward an infirmary should be built for the infirm, sick, decrepit, idle and disturbed patients that are likely to accumulate in an institution intended for, say, 2000. With this nucleus, the cottages can be built up gradually. The paper discusses the details and suggests how modifications can be made for adapting the existing institutions in the various states according to this plan.

**70. Hallucinations and Illusions.**—Tuttle gives an analysis of the patients at Waverly, Mass., as regards these symptoms and discusses their mechanism. He doubts the existence of so-called veridical hallucinations and is inclined to believe that some of these are hallucinations of memory, as described by Royce, that is, the person has an impression at the moment of some exciting experience, which, at a longer or shorter time afterward, impresses him that he has heard of it before its coming and expected it. Tuttle has little faith in telepathy. The theories of hallucination are not considered settled. It is probable that there are certain disturbances of consciousness and lack of firm grasp of mental conditions, favoring the production of these phenomena. Once established they may be continued by habit.

**71. The Hebrew Insane.**—Hyde notices Beadles and Fishberg's statistics and gives some data as regards the admission of Jews at Manhattan Hospital West. He finds a low ratio of syphilis, but a large amount of hysteria and of neurasthenic types. Recovery is most favorable in those under 30 years of age, but they are liable to relapses and re-admission. Paresis occurs in about 18.05 per cent., which he thinks is not as high as the proportion obtained among Christians, but he does not give the figures.

**72. Traumatic Encephalitis.**—Frost reports the case of a large, florid, full-blooded man in the enjoyment of ordinary health, though subject to the strain of an exhausting and exciting occupation, who received a severe blow on the head, causing convulsions and mental disturbance, and died one year later from cerebral apoplexy. There were found postmortem, symmetric areas of softening at the base of the brain in just the position where a blow upon the vertex would act by contrecoup, together with evidences of beginning arteriosclerosis in the brain and kidneys and a gross cerebral hemorrhage in the hemisphere corresponding to the injury, and in which the other lesions were most marked. The hemorrhage was located in the external capsule, an unusual position, invading the lenticular nucleus externally and breaking through the claustrum but not communicating with the ventricle. The symmetric lesions at the temporal lobes were what is designated as localized cerebritis, focal hemorrhagic encephalitis or acute focal encephalitis.

**74. The Pathology of Insanity.**—The results of the autopsies at the Ward's Island Hospital are analyzed by Pettit. The tabulated number was 56 during the past year, 26 of which were paretic, making a total of autopsies of paretics of about 200 out of a population of that class of 2000. The macroscopic appearances were uniform. He is inclined to believe that with further knowledge a condition will be revealed that may be called peripheral paresis, that is, that the specific cause of paresis will be found to exert its morbid influence upon the nerve terminals and capillaries and produce a dystrophic neurosis by direct interference with diastolic metabolic function. Histopathologic changes have been found with this muscular dystrophy where the trophic centers at present recognized have been normal. Further investigation, however, will be required and he is inclined to think there has been a change in the symptomatology of paresis of late years and that at some future time this disease may be isolated from the insanities and treated as a lesion not necessarily involving mental in-

competency. Finally, in some cases there seems to be a self-limitation. The disease may run its specific course without fatality in a small ratio of patients who live many years in a state of instinctive moria.

**75. Unilateral Hydrocephalus with Recurrent Hemiplegia.**—White describes a case, as indicated in the title of his article, in a woman 74 years of age. The attacks were of comparatively short duration and were accompanied by great muscular tenderness and cutaneous anesthesia. The limbs on the paralyzed side showed a marked diminution in size. The hemiplegic attacks were always diagnosed during life as cerebral embolism, mainly because of the thickened arteries, quick recovery and the heart murmur. The autopsy revealed severe internal unilateral hydrocephalus, the only causative lesion found being an obstructive one in the left choroid plexus and the only explanation of its unilateral character being a hypothetical one. He is inclined to consider the condition as due to increased production of fluid from venous congestion of the left choroid plexus caused by excess of hyaloid bodies and a valvular closing of the foramen of Monro confining the excess to the left hemisphere.

**86. Peripheral Speech Defects.**—Ballenger enumerates a number of conditions which cause defects of speech in so-called backward children. Among the nasal conditions he includes septal deflections and spurs, double convexity of septum, nasal polypi, turgescence and hypertrophy of the turbinates, occlusion of the posterior nares, displacement of the columnar cartilage, enlargement of the middle turbinates from hyperplasia or cystic degeneration and anterior soft hypertrophies of the septum. Among the nasopharyngeal and faucial conditions, postnasal adenoids, fibroma or other neoplasms of the nasopharynx, chronic catarrhal thickening of the mucosa of the nasopharynx, hypertrophied or hyperplastic faucial tonsils, adhesions of the anterior and posterior pillars of the fauces to the tonsils, paralysis of the soft palate and uvula, adhesions of the anterior faucial pillars to the base of the tongue, cleft soft palate and uvula and a shortened soft palate as is sometimes found after operation for cleft palate. The lingual conditions are inflammatory adhesions binding the tongue to the anterior faucial pillars and epiglottis, congenital shortness of the geniohyoglossus muscle, tongue tie, enlargement of the tongue and of the lingual tonsils. Laryngeal conditions are also mentioned, including too great strength in the uplifting muscles of the larynx, weakness of the down-pulling muscles of the larynx, laryngitis, singers' nodules, choroiditis nodosa, tubercular inflammation and infiltration, perichondritis, laryngeal rheumatism, catarrhal accumulations, neoplasms and paralysis of the intrinsic laryngeal muscles, while the abdominal and thoracic conditions are tuberculosis in its relation to stammering and irregularity of the respiratory rhythm. He notices also the mental impairment associated with defective speech and nasal and faucial abnormalities, but admits that great imperfection of speech may exist without such impairment, though in nearly all cases "the speech belieth the man." The peripheral causes of defective speech should receive attention in early life during the formative period of language.

**87. Splenectomy.**—Harris and Herzog's paper is a long one, giving a list of the splenectomies for primitive splenomegaly already published, adding two cases of their own, making a total of 19 cases with 14 recoveries and 4 deaths, and 1 in which the result is not stated. The after-history of many of the cases unfortunately is not complete, but it seems probable that recovery does occur after splenectomy. It is advisable to operate as soon as a correct diagnosis can be established, as the dangers and difficulties of the operation increase in proportion to the size of the spleen. The median incision is the one most advisable and in their cases they extended the incision downward so that the lower end of the spleen could be drawn upward. The splenic vessels are then easily approached and ligated. It is probably better to ligate at once than to place a large clamp on the vessels, as the thin veins are apt to tear at the edge of the clamp and the hemorrhage may be difficult to control. After ligating and dividing the pedicle, the spleen may be drawn downward and the gastrosplenic omentum more easily reached.

99. **Seborrhea.**—Schamberg reviews Sabouraud's views in regard to the micro-bacilli of this condition, but does not agree entirely with him as to the evidence of the parasitic nature of seborrhea, aene and baldness, or that the micro-bacillus is not a more or less normal resident of the large sebaceous glands.

100. **Chronic Posterior Urethritis.**—The special form of impotence described by Schmidt is where the sexual feelings are changed to a most painful condition and their excitation avoided. The local findings are enlargement and redness of the caput gallinaginis, inflammatory signs in the verumontanum and other evidences of chronic posterior urethral inflammation. The urethra should be treated by direct application of iodoglycerin solution to the parts, at first weak, afterwards increased in strength, using less quantity and less frequent applications.

101. **New Tissue Formation in the Urethra.**—The following are the conclusions of Dowd's article: "The stringy substance found in the urine during the early period of resolution (three to eight weeks) must not be confounded with the true shreds (three months and on), which are evidence of localized inflammation. The bloody, clot-like string so often seen after dilatation of the urethra, due to contracted meatus, close navicular valve and the like, must not be confounded with the true bloody string, which consists of pus, degenerated epithelium, mucus and blood-cells imbedded in a hyaline matrix. An antiseptic solution should always be used for flushing the canal previous to the instrumentation and afterward an astringent should be used in the same way, this not only for allaying irritation, but for flushing out the evidences of new tissue formation. For diagnostic purposes, the constriction must be stretched above the diameter that already exists and for prognosis, at least two numbers above the normal circular caliber."

119. **Alcohol.**—Hall maintains that ethyl alcohol is the excretion of a fungus and that excretions which are toxic to the organism which excretes them are also toxic to all higher organisms. Alcohol is toxic to the yeast plant, and, from its inherent nature, is toxic to all animal protoplasm.

122. **Text-Book Teaching of Alcohol.**—Crothers reviews the subject of text-book teaching, which has been of late so much criticised, following the same lines of argument as in the communication of Mrs. Hunt, published in THE JOURNAL of March 22 and stating many of the same facts.

129. **Sympathetic Ophthalmia.**—From the three cases which Hale here gives he concludes that the theory of transmigration of bacteria in the production of sympathetic ophthalmia will not account for all the facts, especially where there is a long interval between the infection of the second eye and the injury to the other. The ease of Schmidt-Rimpler, published in the *Deutsche Medicin. Wochenschr.*, No. 27, 1900, in which an echinococcus of one eye was accompanied by sympathetic ophthalmia of the other is still more difficult to explain by this theory. He is, therefore, brought to the conclusion from his own cases and these others that sympathetic ophthalmia is a neuritis which is not produced entirely by the migration of micro-organisms, but that in any case where it has to do with the growth of bacteria it can be only by the irritation of tissues by the toxins thus produced.

140.—See abstract in THE JOURNAL of March 1, p. 604.

141.—Ibid., March 15, p. 724.

142. **Tuberculosis of Cervical Glands.**—This is usually a localized affection and the author in the treatment has been guided by the facts: 1, that a spontaneous recovery may take place wherever destructive degeneration has not occurred; 2, the general condition of the patient must be carefully looked after; 3, when the gland is broken down it should be removed or incised and curetted; 4, also when it remains very large for a long time and does not decrease in size it should be removed; and 5, that when degeneration or abscess formation have occurred within the gland, it should not be allowed to spontaneously rupture, but should be opened, curetted, drained and iodoformized. The so-called radical operation, he thinks, is not

necessary in most cases. It does not save scar and is not a sure and radical cure, increases rather than diminishes the danger of systemic infection and it is a severe task to the patient's endurance. The treatment he usually advises is regulated exercise in the open air, well-ventilated sleeping apartments, good nutritive food, and milk between meals and on retiring. Drugs are seldom necessary. If anemia requires treatment, syrup of iodid of iron is perhaps the best. The patient should retire early, spending as nearly as possible all the hours of the night in sleep. The morning and evening temperature should be recorded and careful record kept of the patient's weight. If the enlarged glands are not broken down, the skin should be thoroughly anointed every night with a 10 per cent. ichthyol ointment. If one or two glands are decidedly larger than the rest and show a tendency to remain so or increase it may be well to make a small incision and remove them, or if any show evidence of having broken down by cheesy tuberculosis incision should be made and they should be opened before they rupture their capsules. In such cases the cavity should be thoroughly curetted and kept open by gauze or a rubber drain for a few days and then treated by a 10 per cent. emulsion of iodoform in glycerin. In the vast majority of cases this treatment will be satisfactory, but not if extensive abscesses have been allowed to form.

144. **Tuberculosis and Arthritis.**—Reilly has collected data of 100 tuberculous patients in the wards of the St. Joseph Hospital, New York, to find out if there may be an antagonism between rheumatism, gout and tuberculosis. In this number there were but six, who, during some period of their lives, had had an attack of rheumatism. In only one case did rheumatism occur after the onset of tuberculosis. In others there was an interval varying from two to ten years between the disappearance of the arthritic phenomenon and the development of tuberculosis. Three of the 6 cases had fibroid phthisis of three or four years' duration with little tendency to the formation of cavities and were in fair general condition. Two of the others had suffered from the disease for about one year, had several large cavities and were considerably emaciated. One of these left the hospital much improved, the other has since died. The sixth case died within nine months of the inception of tuberculosis, which makes a 2 per cent. mortality in the 100. None of the 100 cases had ever suffered from gout or any of the diseases usually classed as being of a gouty or rheumatic origin, with the possible exception of three cases of chronic endocarditis. There was not a single family history of gout. It may be remarked that the neuritis which is quite common in the later stages of phthisis is often mistaken for rheumatism by the patient. All these patients had been employed at work which exposed them to inclement weather much of the time. Alcoholic excesses and loss of sleep, alone or together, had existed in 82 per cent. While these statistics are too limited to be positive proof, there are accessory facts. Croftan has given the same results. He finds in 100 consecutive cases of arthritis only one case of advanced pulmonary tuberculosis. In 200 selected cases of advanced pulmonary tuberculosis there were but three with co-existent arthritic manifestations. He concludes that deposit of the mineral salts of the blood occurs in the lung in arthritides, in and around the areas in which the resistance is lessened, causing a thickening of the tissues, walling off of the areas, lessening the blood supply and then destroying the bacilli. In case of suspected pulmonary phthisis Croftan believes that we may consider it strong corroborative evidence of the existence of the disease when the total percentage of uric acid and alloxuric bases in the urine are persistently low and where there is also absence of polynuclear basophilic granules from the blood. On the other hand, we are justified in making a favorable prognosis in cases of early tuberculosis in which the presence of arthritis may be determined. Bernheim, in the September issue of the *Bulletin Médical de Strasbourg*, confirms Croftan's researches and cites several French writers in support of the statement that there is a pronounced antagonism between gout and tuberculosis. Bronchial asthma, which is generally regarded as a congener of rheumatic intoxication, is seldom associated with fatal pulmonary tuberculosis. It has long been known that a

much more favorable prognosis may generally be given in cases of phthisis pulmonalis which are already affected with mitral regurgitation, which in the vast majority of cases is due to previous rheumatic poisoning. Anders' recent statistics have fully borne out the above statement as to the prognosis in these cases. Harper, of Birmingham, England, has been so convinced of this antagonism that he has employed urea in the treatment of phthisis and has reported a number of cases of apparent arrest of the disease. Various writers have noticed the absence of tuberculosis in the various skin diseases belonging to the arthritic group. Most of us believe that red meats in excess tend to develop the soil on which the specific micro-organisms of rheumatic fever may be developed, while on the other hand we specially recommend this diet for the tuberculous. Most of the cases of permanently arrested pulmonary phthisis develop a decided arthritic taint.

**157. Cesarean Section.**—Cole reports two cases of Cesarean section and enumerates the following points to be considered: "1, thorough asepsis of patient, operators and assistants; 2, expedition in work, as shock must necessarily figure as a factor in every case; 3, diligent efforts in controlling blood loss; 4, a thorough cleansing of the abdominal cavity by gently drying with gauze, avoiding all rough handling of the peritoneal cavity and contents; 5, careful suturing of uterine incision. This last, if not carefully done, may undo all the previous good work." While such operations may occur only once during a lifetime or not at all, it is well that the physician should be able to meet the conditions should they arise. The general practitioner in the practice of obstetrics should be more than a generally useful person, otherwise he will soon sink to the level of the ordinary midwife. Not only should he be able to estimate the amount of contraction, but his experience with normal cases should qualify him to form an opinion as to whether it would be possible for a living child to be born.

2. Posture and Heart Murmur.—Gordon reports and illustrates the effects of posture on the different heart sounds in

morbid conditions. If anyone who has a considerable number of cardiac and anemia cases takes the trouble to examine them systematically, both in the recumbent and sitting posture, he will find that the change from one to the other position produces marked effects on the cardiac sounds. To estimate these correctly one must eliminate the influence of exertion, and the change of posture must be effected by an assistant so that no effort is made by the patient himself. A few pulse beats should be allowed to pass after the change of posture and the observation should be made with a wooden stethoscope. He questions as to the mechanism of these changes and has measured several dozens of chests with a specially designed pair of calipers to find whether the altered chest depth may have its influence. He thinks that this influences to a certain extent some of the murmurs, though further explanation is necessary as the changed murmurs occur in some rigid chests where there is practically no change in the altered posture. Gravity, he holds, as Clifford Allbutt has pointed out, seems to cause an increase of hum in the upright condition. He asks whether it can affect the murmurs in the heart, and figuring out the conditions, he concludes that the two factors, change of chest depth and gravity, together should produce an increase of mitral regurgitant murmur, decrease in mitral stenotic murmurs, increase of tricuspid regurgitant murmurs, and aortic stenotic murmurs, while aortic regurgitant murmurs are scarcely, if at all, affected, and these are the chest effects which he finds are produced. His summary is given as follows: "1. It seems to me that recumbency tends to increase all 'hemic' murmurs except the venous hum, which it tends to obliterate; to increase the murmurs of mitral regurgitation, tricuspid regurgitation and aortic stenosis; to decrease the murmurs of mitral stenosis, and to leave little, if at all, affected the murmur of aortic regurgitation. 2. The effects of gravity and of change in chest depth seem to account for the influence of recumbency. 3. Therefore, in describing and discussing murmurs, which posture modifies the patient's position at the time of observation should be stated."

#### 4. Traumatic Aneurysm Treated by Proximal Ligature.

—The usual rule of tying both ends of the arteries for traumatic aneurysm meets with certain difficulties in cases of diffuse traumatic aneurysm in the axilla, especially in gunshot injuries. Birt reports six cases which show that the ligature of the proximal portion of the arteries alone is sufficient to bring about recovery in each case. In all the cases the wounds run an afebrile and aseptic course.

7. Puerperal Insanity.—The paper is concluded in this issue. Jones finds that the usual opinion of authorities that this type of insanity is most recoverable, is borne out by the facts, though he has known a number of cases to pass into the chronic condition. Relapses, he thinks, are more common than generally believed. As regards the different types, that occurring in early pregnancy is rather favorable; that in late gestation is apt to continue in an exaggerated degree until after confinement and may afterward become chronic. The death rate is highest among the insanities of pregnancy and lowest among the puerperal cases. In lactation insanity one must look out for the general condition of the patient. Albuminuria in puerperal insanity is not common, but when it occurs the prognosis is grave. The pathology of the conditions is discussed and the general toxic theory held by the author, who speculates a little on the method in which the condition is brought about. It is uncertain, he says, and improbable that all forms of puerperal insanity are due to the presence of bacterial poisoning, though it is unquestionable that some are of septic origin. The treatment of the condition varies according to the stage in pregnancy cases. He has little favorable to say in regard to bringing about an abortion. He thinks the condition is usually a recoverable one and may pass off toward the end of pregnancy or after confinement. The most constant vigilance must be kept up by those in charge of the patient. The question of hospital treatment is an important one. The dislike and distrust of the patient towards her husband and friends are often a very serious matter. The impulses to

suicide and homicide are better looked after in an institution. and the nutrition can be better regulated, and the resort to narcotics obviated. The general treatment is that of the parturient female—light dietary, general exercise, bright surroundings, attention to bowel elimination and sleep. The complications which may arise, such as eclampsia, must be met as in the usual indications. He tries, as a rule, not to send the patient away from home so as to avoid the recollections of an asylum and the popular stigma. If the mother can be led to think she is suffering from fever and not brain disease it will help her to avoid and go through future attacks. Nourishment is one of the most important things, and refusal of food one of the most serious symptoms. He does not believe in the use of opiates for producing sleep; chloral and bromids in combination are best. Relapses and return of the mental affection after convalescence are frequently noticed, and it is in this stage that a change from the asylum to the home surroundings or a change of scene may prove beneficial. The conditions of the breast need special attention. He has seen cases admitted during lactation as a result of the indiscriminate use of stimulants. In conclusion he suggests the prophylaxis of this form of insanity by discouraging the marriage of hysteric and neurotic persons, and expresses his firm belief that insanity is and always will be the product of two factors, stress and heredity, and the greater the vitality or resistance of the tissues the greater will be the strain required to overcome it. We should endeavor to raise the resistance against the action of selective toxins and thus improve the chances of the sufferers.

**9. Obliterative Arteritis.**—Gould's second lecture takes up this subject, which has been comparatively neglected. It has hardly found its way into the text-books and is still regarded as a very rare affection, though he does not so consider it, having had 9 cases under his personal observation. The paramount rôle of the inner coat of the arteries must be remembered; it is the one essential portion and the part that suffers. The elastic lamina of the outer surface is a very resistant structure; any hyperplasia of the endothelium or sub-endothelium tissue contracts the lumen by pressure in the direction of least resistance. The direction of the growth is toward the center of the vessel, but disease of the inner coat, especially when the endothelium is involved, very quickly leads to thrombus. While thrombus may be and often is a very rapid process, the growth of the inner coat to such an extent as to obstruct the vessel is always a slower process and slower in direct proportion to the size of the vessel. The blood clot, moreover, may be absorbed and disappear and the vessel when it is closed open out again, but a vessel once closed with sub-endothelial growth is permanently occluded. The chief features of obliterative arteritis, which he considers scarcely a specific disease but rather a pathologic effect of many causes, are: "1. The disease originates in the sub-endothelial layers of the tunica intima of the smaller arteries. In its early stages it is marked by a small-cell infiltration, which later organizes into a loose and vascular connective tissue. 2. This growth narrows the lumen of the vessels and may entirely obliterate it; more often, however, thrombosis occurs and the organization of the clot completes the permanent occlusion of the artery. 3. The disease beginning in the smaller arteries tends to spread in a centripetal direction and may reach even the largest arteries. The thrombosis it excites also often extends rapidly and far toward the heart, much faster and further than the changes in the vessel wall, and the clot may thus spread as far as the aorta. 4. The earliest effect of this diseased artery is pain, then follow other evidences of local ischemia and these may pass on to gangrene. These effects vary with the extent of the vascular obstruction and the efficiency of nature's means of compensation. 5. The disease may be very chronic, slowly progressing for years, or it may run a much more rapid course. Having reached a certain point, arrest may occur and the symptoms may gradually pass away, as the unaffected vessels become more and more efficient substitutes for those that have been occluded. 6. The disease arrested for a time may afterward recur in the vessels of the same limb or elsewhere, and it may attack more

than one vascular area simultaneously. 7. The vascular changes are not always limited to the arteries and endophlebitis may precede or accompany the endarteritis and the venous obstruction then modifies the effect produced on the tissues." A number of cases are reported illustrating the different conditions and the tendency of the disease to attack the vessels in more than one limb. The disease is certainly more common in men than in women, and it appears to be a disease of adult life, not occurring in infancy or old age, though one unique case in an infant has been described which may be of this character. Of all known causes syphilis is perhaps the most certain; influenza, alcoholism, erythromelalgia, cold, contusions, and previous thrombosis or phlebitis may be regarded as more or less important factors. Diabetes sometimes causes gangrene by exciting this disease. As regards treatment in the earlier stages, prolonged rest of the affected part is certainly called for, and also local warmth. Anodynes for pain may be required. Massage carefully applied may assist in opening out of collateral vessels, promoting absorption through the lymphatics and in freeing the muscles and other tissues of their waste products. In the acute stage the parts are too tender for it; it must be very cautiously employed and only used more vigorously when the disease seems to be arrested and we have only its effects to deal with. Small mummified areas may be left to separate naturally, especially in the hand. For the more extensive gangrene, amputation is necessary. The operation should be done high above the gangrenous spot and at a place and by a method that throws the least strain on the vessels. Thus amputation through the lower part of the thigh is to be preferred to disarticulation at the knee and musculocutaneous flaps are to be chosen in preference to skin flaps.

**12. Internal Derangement of the Knee-Joint.**—A number of different lesions in the knee-joint may cause the symptoms, according to Allingham, and some cases presenting these symptoms improve after the joint is open, though no lesion is found. Possibly these may be early instances of tuberculosis of the joint. He does not advocate immediate and indiscriminate opening of the knee-joint in all these cases; in fact, the very opposite is his aim. The first thing, if the case is treated early, is splinting, varying from a period of one to three weeks, followed by massage and passive movement and properly selected exercise for the joint. This gives rest so that the damage may heal, the split cartilage join and the displaced one grow firmly fixed again, and the slackness of the ligaments consequent on distension of the joint be remedied by massage and movement. In a certain percentage of cases, however, this plan will fail. The trouble will recur and these must be operated on. Those cases also in which a quite loose body can be felt to move to widely different positions in the joint and those in which a loosened cartilage protrudes from the joint will not improve without operation. For operation he prefers a vertical incision, one inch to the inner side of the patella and going down to an inch below the head of the tibia, unless, of course, there are special indications for incising elsewhere. This does not divide the extension of the vasti on the tibia and is easily prolonged upward when necessary for examination of the large synovial pouch above the patella. Care must be taken to clip and tie every bleeding part and the joint must be literally squeezed dry before it is closed. The joint should not be washed out with an antiseptic and no drainage should be employed, though occasionally a little flushing with boiled water would wash out a fragment or clot that could not otherwise be found. The strictest asepsis must be followed and his experience favors the removal of the loose semilunar cartilages rather than fixing them. In closing the wound the sutures are to be passed so as to include the cut synovial membrane. The splints can be taken off within a week, and passive movement begun as soon as the skin wound heals and these measures be combined with massage. If in spite of this there is a stiffness of the joint it must be freely moved under an anesthetic and then daily massaged and freely moved to prevent it from recurring. He tabulates 59 cases showing the different types. In case of damage to the semilunar cartilage there are generally these features: "1. Distinct history of injury originating the trouble; 2, a well-

defined site of pain on the inner or outer side of the knee according to the cartilage damaged; 3, no foreign body palpable; and 4, no creaking in the joint. The same features also characterize generally cases in which the lesion affects an alar ligament or consists in localized hypertrophy of synovial membrane. In a case where a loose body is present the symptoms, again, may be exactly similar to those caused by semilunar damage. Sometimes, however, the body will be able to be moved into widely separated portions of the joint and felt in its different situations. Similarly, a very loose semilunar cartilage may sometimes be diagnosed with certainty through its being protruded at the side of the joint. Such a cartilage, however, may be most confusingly imitated by an excrescence due to rheumatoid arthritis." The general result of the operation is highly satisfactory.

**15. Fibro-Myoma.**—After reporting cases Edgar emphasizes the following points: "1. If the tumor be growing steadily larger, remove it, whether the symptoms be slight or severe. 2. If the tumor be stationary as regards size, the treatment will depend on the severity and continuance of the symptoms, the age of the patient and the state of her health. 3. If drugs fail to check hemorrhage, a trial may be made of the Apostoli treatment, or preferably, of curettage of the endometrium, provided the case is not one for more radical measures. 4. Where removal of the tumor is indicated, remember the danger of delay. The weaker the patient and the more complicated the case, the higher the mortality after operation. 5. Unless in certain cases, supravaginal amputation of the uterus is preferable to pan-hysterectomy. 6. When hysterectomy is being performed, one or both ovaries, if healthy, should be preserved. 7. Abdominal enucleation of fibro-myomata, if performed at all, should be limited to cases of the sub-peritoneal variety, and then only when there are no more than two or three tumors present. 8. If the operation of pan-hysterectomy be adopted, perform it by the vagina when the uterus is small; by the combined method when it is large."

**16. Pneumonia.**—The statistics of the Glasgow Royal Infirmary are analyzed by Fraser and tabulated, and show a decided diminution in the proportion of phthisis and an increased mortality from pneumonia. The question whether the number of pneumonia deaths is due to increased number of cases or to increased mortality, or to both, is discussed and it appears that the average case mortality is greatly increased. In 49 years, from 1852 to 1900, the average case mortality for females and males together has risen from 18.7 per cent., of the period 1851 to 1860, to 30.9 per cent., in the period 1891 to 1900, a sudden increase of 8.59 per cent. occurring in the last decade. The increase among males was greater than that among females, while the frequency of the disease is also increased in males though not in females. It would appear, therefore, that: "1. On the whole pneumonia is becoming a slightly more frequent disease in Glasgow Royal Infirmary when compared with all other medical diseases admitted, and 2, that the average percentage mortality shows a marked increase, amounting to 66 per cent. for males and females together; 72 per cent. for males alone, and 29.5 per cent. for females alone."

**18. The Nervous System and the Circulation in the Defense of the Organism.**—Grasset remarks that Doyen's operation on the united twins is a wonderful demonstration *in vivo* of the important part played by the nervous system in the defense of the organism, which has been demonstrated only experimentally before. Animals have been fastened together in such a way that the blood from one passed into the circulation of the other, and in the united twins the blood circulated freely between them. They had the same blood, the same corpuscles, and the tuberculous infection of one proved the inevitable infection of both. The blood carried the tubercle bacillus and its toxins indiscriminately throughout the body of each of the twins. But the reaction was different in each, and was evidently due to the nervous system, which was entirely distinct in each. These facts demonstrate anew how marked and well defined is the individuality of every living being. Even when united or grouped in a colony with a common circulation, each constitutes an independent and distinct entity. Each has its

own individuality in its defense against disease, even when sharing with others the same internal medium.

**21. Technique of Lumbar Puncture in Case of Intraspinal Hemorrhage.**—Tuffier's extensive experience has demonstrated that the cerebrospinal fluid shows traces of blood only from injury of a vein in the soft parts as the needle is inserted, or injury of a vein in the pia or dura mater, or from an actual intraspinal hemorrhage. It is easy to differentiate these three sources of the blood. In the first place, blood issuing directly from a blood vessel coagulates, which does not occur after it has been long diluted with cerebrospinal fluid. If the blood comes from a vein in the tissues outside of the dura, all that is necessary is to push the needle a little farther in. This brings the opening past the vein into the cerebrospinal fluid and the latter flows clear. If this injured vein is in the pia, slightly withdrawing the needle brings the opening away from the pia, and the fluid flows clear. If the blood comes from an actual intraspinal hemorrhage, from fracture of the skull, cerebral hemorrhage, etc., the tint of the fluid remains the same and uniform, no matter how much the position of the needle is altered. The fluid may be more or less reddish, yellow or greenish yellow, according to the degree of hemolysis and the proportion of the normal pigment of the serum, the lutein. When the latter is physiologically abundant, the cerebrospinal fluid becomes yellowish in case of hemorrhage in the cerebrospinal axis. In case no red corpuscles can be detected in the hemorrhagic cerebrospinal fluid, they may possibly have been caught in the crevices of the brain while the pigment diffused, or the hemorrhage may have been absorbed, leaving only the pigment and the blood cells incapable of ameboid movements, the lymphocytes, which remain indefinitely in the cavity into which they have been carried. This occurs also in hemothorax, etc., and the presence of the lymphocytes in such cases should not be called a lymphocytosis. He adds that the yellow tint of the cerebrospinal fluid, free from red corpuscles, is sometimes, exceptionally, the only sign of hemorrhage in the cerebrospinal axis.

**22. External Exploration of Alimentary Canal.**—Vincent points out that inspection, palpation and percussion of the alimentary canal have revealed an unsuspected functional synergy, a functional consensus of the vital phenomena in the various portions of the alimentary canal, both in physiologic and pathologic conditions. Motor insufficiency is always accompanied by secretory insufficiency, hypersecretion by distension of the segment. When the food comes into contact with the wall of the stomach, the entire apparatus, including the liver and pancreas, shares in the vital paroxysm it induces. Some persons react to a pathogenic cause, a cold, errors in diet, etc., by the rapid subsidence of the abdomen. The intestines feel on palpation like wet rags. This subacute condition is in time followed by the return of elasticity and suppleness and restoration to normal both of the tissues and organs and of the functions. This doughy feeling of the abdomen is the objective indication of this subacute condition, and should not be mistaken for digestive marasmus, as it is merely a curable episode unless prolonged or repeatedly induced by errors in diet or treatment. He calls such subjects the weak, and distinguishes another class as the strong. In the latter the resistance to a pathologic cause is indicated by dilatation and hyperplasia of the alimentary canal, revealed by enlargement of the abdomen. This abdominal hypermegaly is a phenomenon of evolution which dominates the entire pathologic life of the individual, and around which cluster the most varied morbid phenomena.

**24. Importance of Persistence of "Negative Effort" in Paralyzed Muscles.**—Régnier has been making practical application of Chauveau's new laws of muscular energy, especially the law in regard to the force, the elasticity, generated by the contraction of a muscle. The muscular effort to raise the arm is called "positive," and the effort to maintain it at a certain height "negative." Régnier finds that these new ideas in physiology are important aids in the prognosis and treatment of paralyzed muscles. The problem is to demand the minimum of effort from the muscle, while inducing the corresponding motor cell in the spinal cord to exert the maximum of energy,

thus overcoming the resistance which the degenerated nerve opposes to the nerve wave. The segment of the limb to be tested is raised by another person to a determined height. Energetic pressure is then applied to the segment of the limb as near to the peripheral limit as possible, the pressure bearing most upon the tendons. It elicits a muscular resistance in the form of negative effort, the intensity proportional to the excitability of the corresponding motor cell. The pressure stimulates the motor cell by simple sensory reflexes and also by the nerve influx from the brain which it elicits or re-enforces. If the muscle does not contract under these conditions it may be possible to induce the "negative effort" by purely reflex action. For example, if the brachial triceps is incapable of opposing voluntary resistance to flexion of the elbow in spite of energetic pressure at the wrist, it may be possible to induce this contraction by having the arm held horizontally, continuing the pressure at the wrist. The patient is then asked to resist the falling of the arm by contracting the deltoid. If during this effort the elbow is flexed, a resistance may be noticed, due to the reflex contraction designed to maintain the rigidity of the lever. The multiplicity of the reflex actions in this case substitutes the nerve wave from the brain, which the pressure is unable to elicit owing to the long disuse of the corresponding cells of the sensory-motor zone. Régnier has found that it is possible to elicit this contraction of voluntary resistance or reflex contraction in more than 50 per cent. of the muscles affected with spinal or neuritic paralysis, even when the degeneration test is positive in every respect. This resistance test is extremely important for the prognosis. He has observed that in every patient the restoration of function was more rapid and more complete in proportion as the response to the test was more perfect. He also found that all treatment proved ineffectual when the response was negative. This resistance contraction is, at the same time, the best treatment of paralysis as it exercises the neuro-muscular system involved, inducing physiologic activity, which is beyond the power of artificial stimuli, even electricity. When the strength of the resistance has been increased by a few weeks of daily séances, the restoration of positive effort can be hastened by salt baths. As the expenditure of energy is proportionate to the degree of contraction and to the weight sustained, the latter factor can be completely suppressed and the weight of the member eliminated by having the patient lie in a salt bath whose density is equal to that of the human body. By this means the patient finds that he is able to execute slight voluntary movements impossible under ordinary conditions. Régnier adds that the latest discoveries in physiology afford a scientific explanation of the results of therapeutic Swedish movements. Ling, the inventor, laid great stress on the "resistance movements," which term has been erroneously restricted since his day to movements to which artificial external resistance is opposed. This is contrary to the principles of his system.

**28. Intranasal Treatment of Dysmenorrhea.**—Ephraim found that cocaineization of the so-called genital points in the nose was successful in arresting the pains accompanying the menstrual period in 18 out of 24 patients whom he had occasion to treat for intense dysmenorrhea. Three to five minutes after the points had been cocaineized the severe pains vanished for several hours, not only while reclining but during violent exercise. Seven of the patients were married. The nasal mucosa was slightly congested in 7 and pathologic in 5. The septum was enlarged in 3 of these and the other 2 presented evidences of rhinitis. In these 2 last patients the cocaine produced no effect. In one patient who was completely relieved of her customary severe dysmenorrhea, the uterus was fastened in retroflexion. His attempts to permanently cure the dysmenorrhea by cauterizing the genital points, were less successful. Only 4 out of the 8 patients thus treated more than six months ago have been permanently freed from their pains. One of the cured patients used to have extremely painful menses and they have now been entirely painless for more than a year. Bipolar electrolysis is the most effective method, but it is so painful that he applied it only twice, using the galvanocautery in the other cases.

**32. Arteriosclerosis in Relation to Cerebral Affections.**—Windscheid describes a complex of symptoms on the part of the nervous system which can be accepted as the direct expression of arteriosclerosis of the cerebral vessels. This is exclusive of hemorrhage, thrombosis, aneurysms and cerebral disturbances secondary to the arteriosclerosis. The symptoms of the condition to which he refers are a certain fatigue and exhaustion of the brain. Subjects thus affected cease to accomplish any new intellectual work. The brain seems to be capable of carrying on its usual tasks but can not undertake anything new. This condition is associated with headaches, vertigo and loss of memory. The headache is usually frontal and persistent, exaggerated by stooping, abdominal pressure and unusual physical exertion. The dizziness is slight, merely an uncertainty in the gait, never sufficient to induce a fall. There is frequently a remarkable intolerance to alcohol. The loss of the memory is generally the symptom that brings the patient to the physician. When this symptom-complex exists coincident with peripheral arteriosclerosis, the diagnosis of arteriosclerotic alterations in the brain is evident. They may occur without peripheral indications of arteriosclerosis. He believes that there is some regulating apparatus which compensates arteriosclerosis of the brain vessels, until some sudden cause disturbs this regulating apparatus and entails the symptom-complex above described. The arteriosclerosis may have long existed but caused no symptoms as long as the regulating apparatus was in working order. This is probably the cause of the disturbances which follow a slight injury to the skull. The nervous troubles observed in such cases, traumatic hysteria, etc., are due to the already established arteriosclerosis. The assumption of a hitherto latent arteriosclerosis of the brain suggests an explanation of the obscure so-called functional cerebral affections, especially certain manifestations of hysteria.

**33. New Clinical Standpoints in Regard to Arteriosclerosis.**—Grassmann describes arteriosclerosis as in one sense a diffuse neoformation in the walls of the vessels. Its frequently progressive course stamps it as of malignant nature. The process is one of hypertrophy, although frequently associated with evidences of inflammation. Hasenfeld has established that certain large tracts of vessels can be affected with a slight or moderate degree of arteriosclerosis, while all the other vessels are intact. He found on comprehensive study of the vascular system in fourteen cadavers that arteriosclerosis of the visceral region does not necessarily entail hypertrophy of the left ventricle so long as the lesions are restricted to the lower portions and do not involve the visceral arteries nor the aorta above the diaphragm. It is a comparatively recent discovery that arteriosclerosis frequently occurs in the small and minutest arterioles over large areas and that the consequent resistance causes increased pressure and enlargement of the heart. Huchard and Runeberg believe that this is due to a vasomotor constriction from toxins in the circulation, but this assumption has not yet been proved. The permanency of the exaggerated arterial pressure in arteriosclerosis is an important point for its differentiation. Some attribute great importance to the serpentine course of the arteries if the subject is under 25 or 30 years of age, and has inherited a tendency to arteriosclerosis. Sakorrhaphos found that all persons of this class in his experience died in middle age. Gehrhart has noticed that the pulse in two symmetrically located arteries may vary by two to ten beats. This is especially marked when the arteriosclerosis involves the most proximal portion of the artery. Another sign is what Huchard calls the stability of the pulse, that is, the lack of the normal decline of six to eight beats in the pulse when the subject reclines or sits after standing. The pulse may even be more rapid when the subject reclines, and when the second aortic sound is more pronounced in addition the diagnosis of arteriosclerosis is evident. The enlargement of the heart in arteriosclerosis is not restricted to the left ventricle but involves both. Hull and Sutton distinguish an arterio-capillary fibrosis as distinct from arteriosclerosis. Runeberg has recently pointed out that in case of coronary arteriosclerosis, in addition to the familiar symptoms, the first

heart sound becomes a dull murmur while the pulse is peculiarly soft. Study of the clinical picture of coronary arteriosclerosis suggest an analogy between it and the affection known as intermittent limping or claudication. In both cases the vessels are narrowed so that the supply of arterial blood is insufficient and is rapidly used up, with consequent exhaustion of the muscles. The resulting pain is cured by repose. The partial or total abolition of the pulse in the arteries of the feet indicates an arteriosclerotic foundation for the pains and functional disturbances. Formication, numbness, etc., in the peripheral parts are frequently factors in the obstinate insomnia of arteriosclerosis. Pruritus can likewise be traced to arteriosclerosis in many instances. Acute renal affections are liable to produce the same clinical picture as arteriosclerosis, but in these cases it is transient. Von Noorden found arteriosclerosis in 155 out of 343 diabetics, and Fleiner noted that arteriosclerosis was frequent in the vessels of the pancreas in cases of diabetes. Grabe has described cases in which the diabetes might possibly be ascribed to the arteriosclerotic alterations noted in the floor of the fourth ventricle. Little progress has been made in treatment during the last few years, but it is frequently possible by prophylactic measures to keep arteriosclerosis under control and arrest it at a moderate stage. Vierordt reports that 50 per cent. of his patients were favorably influenced by treatment with potassium or sodium iodid. Edgren and others report similarly favorable results from the iodine salts kept up in small doses for months and years. The benefit is especially marked in angina pectoris. Rosenbach and Schrötter denounce this treatment. Rumpf orders food as free from lime as possible, excluding milk for this reason. When arteriosclerosis is recognized in the early stages much can be done in the line of prevention by regulating the mode of life. All agree that severe physical exercise in sport or labor, especially when associated with excessive use of alcohol, is an important factor in its production.

**34. Hyperkeratosis Lacunaris Pharyngis.**—Arnsperger reports from Erb's clinic a case of this rare affection. The patient was a young girl of 17, subject to recurring sore throat. She noticed white patches in the throat during an acute attack of folliculitis. When the physician attempted to remove them he found that they were hard and required considerable force for their extraction. A similar keratosis has been described by various writers and treated with caustics, etc., or by extirpation of the tonsils. In the present case daily painting with silver nitrate had no effect and each of the horny plugs was scraped out with the sharp curette under cocaine. The tonsils were freed in four sittings, but six more were required for the removal of the other plugs in the wall. This relieved the patient from all her disturbances and there has been no recurrence during the six months since. He advocates this energetic procedure at once without wasting time on gargles and other measures which are liable to prove ineffective. The leptothrix and other micro-organisms found in such cases are probably a secondary invasion.

**35. Antitoxic Power of Alcohol in Tuberculosis.**—Mircoli announces that his experience has fully confirmed Buchner's assertions in regard to the favorable effect of the local application of alcohol in tuberculosis on the principle of Salzedel's alcohol compresses for treatment of phlegmons, lymphangitis, mastitis, etc. Mircoli was commissioned to test the antitoxic power of the serum in numerous subjects to establish standards for Maragliano's aqueous antituberculosis serum. He found that serum and ascitic fluid from subjects addicted to alcohol possessed exceptional antitoxic power except in case of organic lesions from its abuse. This power increased under treatment with Maragliano's serum much more rapidly than in persons not accustomed to alcohol. He found that the dock hands of Genoa, although exposed to vicissitudes of weather, inhalation of coal and grain dust, etc., do not suffer from tuberculosis more than other workmen. Each drinks on an average three quarts of wine a day. The statistics at his clinic indicate that tuberculosis is less frequent in alcohol drinkers. The general effect of the alcohol seems to parallel that of the Maragliano serum although it is much less intense. It evi-

dently confers upon the organism the power to neutralize the toxins of the tubercle bacillus. The antitoxic action of the alcohol, supplementing its sclerosing action, works against the spread of tuberculosis. Mircoli's experiences, therefore, tend to prove that a copious but not excessive use of alcohol is distinctly beneficial in tuberculosis. Maragliano recommends it in the form of brandy in milk. The benefits that have been derived from alcohol in typhoid fever, scorbutus, pyemia, etc., are probably due to the formation of antitoxin which it induces. He adds that the moral and sentimental fear of favoring the abuse of alcohol should not deter from the dispassionate scientific study of the matter.

**45. Frenkel's Therapeutic Exercises.**—Frank was at first a patient and then an assistant at Frenkel's establishment, and reports the great success of his method. No apparatus is used, except lines marked on the floor, and the exercises are rigorously individualized. He regulates the length of the exercise by the patient's pulse, which reveals incipient fatigue before he is himself conscious of it. The aim is to induce co-ordinated movements and all unnecessary muscular effort is avoided. Many of the exercises are done while the patient reclines. He discriminates carefully between the disturbances caused by ataxy and those caused by hypotonus which frequently precedes or accompanies the former. Its most striking symptom is the bending of the knee backward. Frenkel asserts that every case of ataxy can be improved and the majority of patients restored to their business. The benefit has been permanent in his patients. Six to eight years have passed in many cases without recurrence. The old idea that tabes is constantly progressive was based on the fact that the co-ordination became progressively worse on account of the lack of exercise from the enforced repose.

**47. Signs of Commencing Pregnancy.**—Schenk has been testing on 61 patients the value of three signs of commencing pregnancy: 1, the increase in size of the uterus in the sagittal diameter; 2, Hegar's sign of the compressibility of the lower segment of the uterus, and 3, the sign noted by Braun and Piskacek, the asymmetrical shape of the uterus. One side seems larger than the other, especially marked in the upper corner. This phenomenon is accompanied by a deep groove outlining the enlarged corner, which is always softer than the other side. He calls this the "Ausladung" sign, which is an architectural term signifying a protuberance or projection. Schenk found that the increase in the sagittal diameter is a constant and most valuable sign in the very earliest stage of pregnancy, while Hegar's and the Ausladung sign are of subordinate importance. By the end of the second month, however, the latter predominate, and Hegar's sign is most constant and important, but the absence of these signs does not absolutely exclude a pregnancy. By the third month the Hegar sign can be noted in almost every case and the Ausladung sign in more than 75 per cent. of all cases. The latter is probably due to the extramedian location of the ovum and coincides with the formation of the placenta. When there is no lateral nor median protrusion in the walls of the uterus front or rear, and the lower segment does not show evidences of compressibility, the idea of existing pregnancy can be discarded with almost certainty.

**52. Pertussis and Its Treatment.**—Frieser advocates the general adoption of antitussin in the treatment of pertussis, as the results attained to date indicate that it has efficacy in aborting and curing established cases. It is an organic preparation of fluorin, a salve consisting of 5 parts difluordiphenyl in 10 parts vaselin and 80 parts lanolin. It is rubbed into the skin of the neck, chest and back. The relief was almost immediate in the fifteen cases in which Frieser has applied it, and in others that have been published.

**54. Venesection in Uremia After Scarlet Fever.**—Springer reports five cases which proclaim the benefit to be derived from venesection supplemented by saline infusion in uremia in the course of post-scarlatinal nephritis. The severe cerebral symptoms and tense pulse subsided almost at once. He recommends venesection without losing time with narcotics and

other measures, whenever the uremic symptoms become alarming in children after scarlet fever.

**61. Primary Pigmented Syphilids.**—Moraitis was able to find only six cases of primary pigmented syphilids published during the last seven years, and only one patient was a man. He has had occasion to observe two and found it impossible to cure the patients, although the other manifestations of the syphilis were easily suppressed. In one of his cases the pigmentation spread like a network over almost the entire trunk, leaving small islands of sound skin.

**62. Indications for Abortion in Pulmonary Tuberculosis.**—Zanoni recommends interrupting the pregnancy in a woman with pulmonary tuberculosis if the infection is comparatively recent, not older than four to six months, and the pregnancy has not passed beyond the third month. The patient must also offer evidence that nourishment can be taken and that the loss in weight observed is due to the nausea, etc., of the pregnancy and not to the tubercular process. The pulse should not be above 100 in the morning after five minutes of absolute repose, without cough. The question of the interruption of pregnancy in chronic disease is to be discussed at the approaching international congress of gynecology to be held at Rome next fall. Zanoni describes a case in which the above conditions were fulfilled and which he therefore treated by prompt abortion, restoring the patient when she was apparently in a rapid decline in a fourth pregnancy. The cough, sputa, and the physical signs of the tuberculosis had vanished in fifty days after the abortion and the patient gained more than a dozen pounds in three weeks. She received five injections of anti-tuberculosis serum and a brief course of caecodylic medication.

**69. To Obtain Rapid Proliferation of Tubercle Bacilli.**—Francesco corroborates the value of Hesse's method of growing the tubercle bacillus. The superior proliferation is probably due to the presence of mucus, which is a favorable medium for it, and also to the slight nutritive value of the medium, which impedes the rapid development of the common pyogenic germs. It is a mixture of agar and somatose and the mucous sputum is spread over its surface in a Petri dish.

**75. Hemorrhage After Ablation of Tonsil or Adenoids.**—Lunin has had five cases of severe hemorrhage after operations of this kind. He describes them in detail. One patient in Bryson Delavan's experience bled to death from merely digital exploration of the region. Anemia also predisposes to hemorrhage. Three of his personal cases were very anemic children. Cardiac affections are another contra-indication, especially enlargement of the left ventricle. Arteriosclerosis is so seldom observed in children that it can scarcely be included in the contra-indications. The operator should also be on the lookout for anomalies in the nasopharyngeal cavity, such as the so-called *vertebra prominens*. A superficial examination might mistake this prominent vertebra for a retropharyngeal abscess or tumor. The malformation most important from this point of view is some abnormal course or projection of a blood vessel. Schmiegelleff has reported a fatal hemorrhage from injury of the internal carotid artery. Others have observed a pulsating vessel on the rear wall of the pharynx, assumed to be an abnormal ascending pharyngeal artery or a branch of the internal carotid. The application of cocaine also favors hemorrhage, as the vaso-constricting action of the drug is followed by a relaxation amounting almost to paralysis. This, of course, does not apply to the hemorrhage which occurs several days after the operation. If a scrap of the tonsil is left hanging by its mucous membrane after the operation, it acts like a foreign body and not only interferes with breathing and swallowing, but is liable to induce hemorrhage or maintain it if already established, as he had occasion to observe in his personal experience. Another important factor in the production of hemorrhage is an acute catarrhal affection of the upper air passages. This entails congestion and also a tendency to cough, both of which favor hemorrhage. He states that as the hemorrhage is liable to occur soon after the operation, he keeps the patient until all danger from the effect of the cocaine is

past. He then dismisses him with strict injunctions to keep very quiet for the following six days. In case of heedless or very lively children he insists that they must stay quietly in bed for six days, with light food, no coffee, tea nor alcoholic drinks. He has witnessed severe hemorrhage occur as late as the fifth and sixth days in consequence of physical exertion. Among the measures which have proved effective in arresting the hemorrhage are injections of iced or hot water, of tannin, ferropyrin, suprarenal extract, betol, dermatol, etc. Lunin found a 5 per cent. tepid solution of gelatin successful in one of his cases. Tamponing usually proves effective.

**85. Syphilis of the Alimentary Canal.**—Soboleff describes a case of syphilis affecting the large intestine. He remarks that a lesion of this kind may be suspected when severe pains develop suddenly, accompanied by extreme depression but no fever. Syphilitic involvement of the alimentary canal is especially liable to occur during the third stage of the disease, less frequently during the second. Syphilitic manifestations elsewhere are an aid in the diagnosis, but their absence does not preclude the possibility of the affection. It has always been rapidly cured by specific treatment, but is liable to terminate fatally if not recognized in time.

**95. Treatment of Papilloma Laryngis in Children.**—Lindt describes a case of constantly recurring soft papillomata on the vocal cords of a four-year-old boy who had been hoarse from infancy. After two years of vigilant treatment in the hospital, repeated extirpation of the tumors by tracheotomy or laryngo-fissure, intubation, etc., the tendency to the formation of papillomata seemed to have died out, and the boy was dismissed in good health and with only a slight trace of hoarseness in his speech and no respiratory disturbances nor stridor at any time since. Radical extermination of the papillomata has been only exceptionally successful in such cases, but the fact seems to be established that after a certain length of time, months or years, the tendency to papillomatous proliferation is lost. Lort's catheters render great assistance as it is possible to remove the tumors with them without injury to the most wildly struggling child. Lindt derived the greatest benefit from a glass canula with a large opening in the side which was inserted in the larynx and fastened by threads emerging from the tracheal wound and passing around the neck. The opening was closed during the day and the child breathed naturally. At night the plug was removed and he breathed through the opening. The removal of the papillomata is always indicated, as they will interfere with breathing and speaking even if they do not increase in size, and there is always a possibility that they will not recur. When the case comes under treatment just as the tendency is waning, the results of a single operation may prove brilliantly successful. Otherwise extreme patience and perseverance are indispensable.

**98. Surgical Intervention in Gastric Affections.**—Huber reviews the ultimate course of 62 cases of gastric affections which he had referred to the surgeon. They include 34 patients with carcinoma, 23 with benign stenosis of the pylorus, 1 of severe gastroparesis and 2 of stenosis from compression by tumor elsewhere. Seven of the patients with carcinoma died from the results of the operation. The longest survival after gastrectomy was 781 days and after gastro-enterostomy was 557, except one patient operated on in 1900, who is still living, and 3 in 1901. There was no palpable tumor in 9 of the cases, all men. In 76 per cent. of the cases free hydrochloric acid was absent and in 73.3 per cent. the presence of lactic acid was noted. Vomiting had been observed in all but 5 cases. Motor disturbances were noted in 100 per cent., severe in 94 per cent. Long bacilli were found when lactic acid was present in all but one case. Yeast fungi and sarcine were found in 11 out of the 34 cases; in 6 out of the 7 with free hydrochloric acid and in 5 of the 25 without. A symbiosis of long bacilli and sarcine was observed twice. Coffee-dregs vomit occurred in only 5 cases. It is evidently a sign of a late phase of the carcinoma. In 20 cases the symptoms had lasted from six to twelve months. The age of the patients was 30 to 50 in half of the total number, the maximum occurring between 41 and 50.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

REPORT OF THE MINISTER OF AGRICULTURE FOR THE DOMINION OF CANADA, for the Year Ending Oct. 31, 1901. Paper. Pp. 173. Ottawa: S. E. Dawson. 1902.

TWELFTH ANNUAL REPORT OF ST. MARY'S HOSPITAL. Conducted by Sisters of St. Francis. Paper. Pp. 30. Rochester, Minn.: Daily Bulletin Print. 1902.

PROCEEDINGS OF THE ORLEANS PARISH MEDICAL SOCIETY. Issued March 1, 1902. Paper. Pp. 22. New Orleans: Published by the Society.

BULLETIN OF IOWA INSTITUTIONS. October. Published Quarterly. Paper. Pp. 537. Atlantic, Iowa: Telegraph Printing Co. 1901.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., March 13 to 19, 1902, inclusive:

James K. Ashburn, contract surgeon, leave of absence for one month granted, to take effect about April 1, 1902.

William N. Bispham, lieutenant and asst.-surgeon, U. S. A., from Cabana Barracks, Cuba, to duty at Fort Totten, N. Y.

Joseph J. Curry, contract surgeon, now at the General Hospital, Fort Bayard, N. M., to report in person to the commanding officer of that hospital for duty.

John S. Fogg, captain and asst.-surgeon, Vols., on account of physical disability, is honorably discharged from the service of the United States, to take effect May 25, 1902, and leave of absence is granted until that date.

Clyde S. Ford, lieutenant and asst.-surgeon, U. S. A., leave of absence for two months granted.

Fletcher Gardner, contract surgeon, now at Bloomington, Ind., to proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

George L. Hicks, contract surgeon, from temporary duty at Fort Totten, N. Y., to duty with troops or recruits en route to San Francisco, Cal., and Manila, P. I., and for subsequent assignment in the Division of the Philippines.

William F. de Niedeman, major and surgeon, Vols., leave of absence on certificates of disability granted from the Division of the Philippines extended one month on account of sickness.

William M. Roberts, lieutenant and asst.-surgeon, U. S. A., from duty in the Division of the Philippines to post duty at Fort Sill, Okla.

Erwin I. Shores, contract surgeon, former orders amended so as to direct him to proceed to his home, Elmira, N. Y., for annulment of contract.

William J. S. Stewart, captain and asst.-surgeon, Vols., recently appointed and now at Washington, D. C., to report for assignment to duty with troops or recruits that may be sent to San Francisco, Cal., and on arrival there to report for duty on a government transport.

In addition to the above, orders were issued during the week assigning medical officers to duty on boards to examine officers of the Army for promotion, as follows: At Fort Ethan Allen, Vt., Major Marlborough C. Wyeth, surgeon, U. S. A., and Charles B. Mittelstaedt, contract surgeon; at Fort Keogh, Mont., J. Samuel White, contract surgeon; at Fort McPherson, Ga., Major William D. Crosby, surgeon, U. S. A., and Joseph F. Siler, contract surgeon; at Fort Riley, Kan., Major Paul Shillock, surgeon, U. S. A., and Lieut. Robert N. Winn, asst.-surgeon, U. S. A.; at Fort Sam Houston, Tex., Major Charles F. Mason, surgeon, U. S. A., and David M. Roberts, contract surgeon; at San Francisco, Cal., Major Henry S. Kilbourne, surgeon U. S. A., and Lieut. Henry S. Greenleaf, asst.-surgeon, U. S. A.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending March 22, 1902:

Medical Director N. M. Forebec, commissioned a medical director from Jan. 26, 1902.

Medical Inspector S. H. Dickson, commissioned a medical inspector from Jan. 26, 1902.

P. A. Surgeon E. J. Grow, commissioned a passed assistant surgeon from June 3, 1901.

P. A. Surgeon E. G. Parker, commissioned a passed assistant surgeon from Jan. 10, 1902.

Asst.-Surgeon C. M. Oman, detached from the *Constellation* and ordered to report to the Commandant of the Marine Corps, Washington, D. C., to accompany a detachment of marines to the Asiatic Station.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended March 20, 1902:

Surgeon Preston H. Bailhache, leave of absence for 5 days from March 13, 1902, under paragraph 179 of the regulations.

Surgeon G. M. Magruder, granted extension of leave of absence, on account of sickness, for one month from February 22.

P. A. Surgeon C. P. Wertenbaker, to proceed to Lincoln, Neb., for special temporary duty.

Asst.-Surgeon H. C. Russell, granted leave of absence for five days from Feb. 13, 1902, under paragraph 181 of the regulations.

Asst.-Surgeon H. B. Parker, to proceed to Mobile, Ala., for special temporary duty.

Asst.-Surgeon M. J. White, relieved from duty at the Marine Hospital, San Francisco, Cal., and assigned to special duty at San Francisco from March 19.

Asst.-Surgeon W. C. Hobdy, detailed as inspector of unseviceable property at Savannah Quarantine.

Asst.-Surgeon T. F. Richardson, to proceed to Philadelphia, Pa., for special temporary duty.

Asst.-Surgeon D. H. Currie, relieved from duty at Hygienic Laboratory, to take effect March 29, 1902; relieved from special temporary duty at San Francisco, Cal., and assigned to duty at San Francisco.

Asst.-Surgeon J. M. Holt, granted leave of absence for seven days from March 14.

A. A. Surgeon B. Y. Harris, leave of absence granted for fifteen days by Department letter of Feb. 19, 1902, revoked.

A. A. Surgeon J. F. McCormac, granted leave of absence for fifteen days from March 28.

A. A. Surgeon R. T. Walker, granted leave of absence for five days from April 8.

A. A. Surgeon W. O. Wetmore, granted leave of absence for fourteen days from April 3.

Senior Pharmacist E. S. Maguire, leave of absence for thirty days granted by Department letter of Feb. 4, 1902, revoked.

Senior Pharmacist R. H. Gibson, granted leave of absence for twenty-five days from March 29.

### APPOINTMENTS.

Walter L. Savage, of New York, appointed acting asst.-surgeon for duty at Buffalo, N. Y.

Albert F. Stuart, of Maine, appointed acting asst.-surgeon for duty at Portland, Maine.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended March 21, 1902:

#### SMALLPOX—UNITED STATES.

Alabama: Birmingham, Feb. 1-28, 12 cases.

California: Los Angeles, March 1-8, 1 case; Sacramento, March 1-8, 1 case; San Francisco, March 2-9, 6 cases.

Colorado: Denver, March 1-8, 5 cases.

Florida: Jacksonville, March 8-15, 9 cases.

Illinois: Belleville, March 8-15, 2 cases; Chicago, March 12-19, 7 cases.

Indiana: Elkhart, March 8-15, 1 case; Evansville, March 8-15, 4 cases; Indianapolis, March 8-15, 13 cases; Michigan City, March 10-17, 1 case; Terre Haute, March 8-15, 2 cases.

Iowa: Clinton, March 1-8, 3 cases.

Kansas: Wichita, March 8-15, 2 cases.

Kentucky: Covington, March 8-16, 11 cases; Lexington, March 8-15, 1 case.

Louisiana: New Orleans, March 8-15, 3 cases imported.

Maine: Portland, March 8-15, 2 cases, 2 deaths.

Maryland: Baltimore, March 8-15, 1 case.

Massachusetts: Boston, March 8-15, 21 cases, 4 deaths; Cambridge, March 8-15, 5 cases; Chicopee, March 8-15, 1 case; Haverhill, March 8-15, 1 case; Holyoke, Feb. 22-March 15, 25 cases;

Malden, March 8-15, 2 cases; Newburyport, March 1-15, 2 cases, 1 death; Somerville, March 8-15, 1 case.

Michigan: Detroit, March 8-15, 6 cases; Ludington, March 8-15, 13 cases.

Minnesota: Minneapolis, March 1-15, 29 cases.

Montana: Butte, March 2-9, 1 case.

Nebraska: Omaha, March 8-15, 45 cases; South Omaha, March 8-15, 80 cases, 1 death.

New Jersey: Camden, March 8-15, 3 cases; Newark, March 8-15, 32 cases, 6 deaths.

New York: Binghamton, March 8-15, 1 case; New York, March 8-15, 65 cases, 11 deaths; Yonkers, March 7-14, 1 death.

Ohio: Chillicothe, March 8-15, 2 cases; Cincinnati, March 7-14, 25 cases; Cleveland, March 7-14, 3 cases.

Pennsylvania: Allegheny City, March 8-15, 6 cases; Lebanon, March 8-15, 2 cases; Norristown, March 8-15, 1 case; Philadelphia, March 8-15, 53 cases, 6 deaths; Pittsburgh, March 1-15, 9 cases.

Rhode Island: Providence, March 8-15, 1 case; Warwick, March 7-14, 2 cases.

Tennessee: Memphis, March 8-15, 14 cases.

Texas: San Antonio, Feb. 1-28, 9 cases.

Utah: Salt Lake City, March 8-15, 1 case.

Washington: Tacoma, March 2-9, 9 cases, 1 death.

Wisconsin: Green Bay, March 9-16, 5 cases; Milwaukee, March 8-15, 2 cases.

#### SMALLPOX—FOREIGN AND INSULAR.

Porto Rico: Ponce, March 3, several cases reported.

Austria: Prague, Feb. 15-March 1, 11 cases.

Belgium: Antwerp, Feb. 15-March 1, 34 cases, 8 deaths.

Brazil: Pernambuco, Jan. 15-31, 65 deaths.

Canada: Halifax, March 8-15, 1 death; Quebec, March 8-15, 20 cases, 1 death.

Colombia: Panama, Feb. 24-March 10, 15 deaths.

France: Paris, Feb. 22-March 1, 2 deaths; Rheims, Dec. 1-8, 1 case; Roubaix, Feb. 1-28, 1 death.

Great Britain: England—Liverpool, Feb. 22-March 8, 33 cases; London, Feb. 15-March 1, 881 cases, 139 deaths; Sheffield, Feb. 22-March 1, 1 case. Scotland—Dundee, Feb. 22-March 1, 7 cases;

Edinburgh, Feb. 15-March 22, 1 case; Glasgow, Feb. 28-March 7, 22 cases, 10 deaths.

India: Bombay, Feb. 11-18, 8 deaths; Calcutta, Feb. 8-15, 2 deaths; Karachi, Feb. 9-16, 2 cases, 1 death.

Italy: Rome, Jan. 11-18, 1 death.

Mexico: Mexico, March 2-9, 3 cases, 1 death.

Russia: Moscow, Feb. 8-22, 18 cases, 12 deaths; Odessa, Feb. 15-March 1, 1 case. St. Petersburg, Feb. 8-15, 7 cases, 1 death.

Uruguay: Montevideo, Feb. 5, 32 cases.

#### YELLOW FEVER.

Dutch Guiana: Paramaribo, Jan. 1-31, 5 cases, 3 deaths.

Mexico: Vera Cruz, March 1-8, 8 cases, 4 deaths.

#### CHOLERA.

India: Bombay, Feb. 11-18, 6 deaths; Calcutta, Feb. 8-15, 61 deaths.

#### PLAGUE.

India: Bombay, Feb. 11-18, 663 deaths; Calcutta, Feb. 8-15, 120 deaths; Karachi, Feb. 9-16, 60 cases, 47 deaths.

Japan: Nagasaki, March 13, present.

### REPORT OF CASES TREATED WITH ROENT- GEN RAYS.

WM. ALLEN PUSEY, A.M., M.D.

PROFESSOR OF DERMATOLOGY IN THE UNIVERSITY OF ILLINOIS.  
CHICAGO.

#### TUBERCULOSIS OF THE SKIN.

CASE 1.—Referred to me by Prof. H. B. Favill of Rush Medical College. Woman, aged 38, with extensive lupus involving the chin, cheeks, and neck of four years' duration; healed with healthy soft white scars after five months. This patient has been well now a year and a half and shows no sign of recurrence. This case has been reported in detail.<sup>1</sup>

CASE 2.—Referred to me by Prof. A. J. Ochsner of the University of Illinois. Lupus of the nose in a girl 16 years old of two years' duration; healed with healthy scars after five months; practically no deformity. This patient has been well for a year and there is no evidence of recurrence. The case has been reported in detail.<sup>2</sup>

CASE 3.—Mrs. A., aged 38, fifteen years married, was referred to me in March, 1901, by Dr. E. A. Matthaei. She has never had a serious illness except vesical calculus and cystitis seven years ago, which were relieved by operation, and has never had any sort of skin eruption, except the one on her chin. Her history gives no suspicion of syphilis. She has four healthy children living and has had one miscarriage of a healthy fetus between the third and fourth months. Her family history is without significance, except that her father died at the age of 49 of chronic lung trouble. The patient is spare-built and not very vigorous-looking, but there is no organic disease.

When she came to me in March, 1901, there were two hypertrophic patches, one on the tip of the chin, the other under the chin, which are well shown in the accompanying photograph, Fig. 1. These consisted of closely set groups of waxy, glistening, almost translucent tubercles, which at a distance looked very much like patches of zoster. The first patch to develop, the one under the chin, appeared about seven years ago as a pinhead-sized lesion around which other lesions gradually developed. This patch was cut out, but recurred in the scar, and two years later the group of lesions appeared on the tip of the chin. Since that time the disease has persisted in spite of treatment and gradually increased to its present condition. The scar in the center of the patch under the chin, resulting from the previous operations, produced a similarity in appearance to syphilis, which was confusing.

The case was first shown by me in March, 1901, at the Chicago Dermatological Society as a case of hypertrophic lupus. There was then a difference of opinion between hypertrophic lupus and tubercular syphilide. The case was afterwards shown at the American Dermatological Association where most of the members, I believe, agreed in the diagnosis of hypertrophic lupus. The microscopic findings were not conclusive and in order to exclude syphilis the case was for

two and a half months put under full doses of iodides and mercury and mercurial ointment locally. This treatment had no effect.

After the failure of mixed treatment the case was put under daily x-ray exposures, in June, 1901. The effect was not prompt, but after two months considerable erythema was produced, which was accompanied by marked shrinkage of the lesions. The exposures were continued until August 26, with the production of an acute dermatitis, and by this time the tubercles had shrunken until the surface was flat. The dermatitis was curiously enough confined sharply to the diseased area. Since its first disappearance—seven months ago—there has been no recurrence of the disease. The areas are still red from exposures which the patient has recently had. The only scarring is that which had existed before treatment with x-rays was begun. The present condition is shown in the accompanying photograph, Fig. 2.

CASE 4.—I have under treatment a fourth case of lupus which was included in a former report.<sup>3</sup> It is a very severe case of at least twenty-five years' duration in a woman 41 years old. She had had all sorts of treatment and in October, 1898, the diseased area was removed and a plastic operation for the restoration of the nose and the central part of the face done. The disease recurred in the scar and has since involved the nose and all of the parts around. The nose has been almost entirely destroyed since the recurrence. The disease, which has been under treatment more or less constantly for a year, has not spread in that time, which is in marked contrast to the history of the previous year, but it has not been eradicated. The result thus far in this case is similar to those reported by Finsen in cases where the disease has recurred after plastic operations. I have recently treated her much more vigorously than ever before, with very considerable improvement in her condition and in view of this and the fact that we have succeeded in stopping the spread of the disease, I still have hopes of curing her.

I have had under treatment two other patients who were thought to have cutaneous tuberculosis and who have gotten entirely well while having x-ray exposures. The diagnosis, however, in neither of these cases was fully established and both patients had other treatment besides the use of x-rays, so that in my opinion they are not entitled to consideration in this connection.

The results obtained in Cases 1, 2 and 3 are, I believe, as good as can possibly ever be hoped for by any method. There has been no destruction of healthy tissue in getting rid of the disease and less scarring could not possibly remain after disease as extensive as these cases had. The scars are white, soft, pliable and, indeed, in Cases 2 and 3, are hardly to be called scars. As to the permanency of the results, Case 1 had been well eighteen months, Case 2, twelve months, and Case 3, six months, and none shows any evidence of recurrence. But grant that recurrences should take place, there is every reason to suppose it can be controlled by the same method without scarring or pain. When one contrasts such re-

1. THE JOURNAL A. M. A., Dec. 8, 1900.

2. Ibid., Sept. 28, 1901, 821.

sults with those obtained by former methods of treatment, and remembers the endless routine of pain that the patients suffered in treatment, the fact that this treatment is painless becomes no small consideration.

#### EPITHELIOMA.

CASE 5.—This case was referred to me by Prof. John L. Porter of the University of Illinois. The patient was a woman, aged 68, with extensive epithelioma of shoulder of fifteen years' duration. The disease entirely disappeared April, 1901, after two months and a half of treatment, with the formation of healthy scars. There is no evidence of recurrence after a year.

This case was reported in detail.<sup>2</sup> Since that time Dr. Ludvig Hektoen, Professor of Pathology in Rush Medical College, has very kindly examined my slides from the case and given me the following opinion: "I have examined the sections from Mrs. C.'s shoulder, both yours and those from 1894, and in my opinion there is no question as to the correctness of the diagnosis of carcinoma (rodent ulcer)."

The histological character of the scar tissue is shown in the accompanying photo-micrograph (Fig. 3) of a section of tissue taken from the shoulder at the site of the largest ulcer.

CASE 6.—Mrs. T., aged 68, was referred to me by Dr. Martin F. Engman of St. Louis, late House Surgeon, New York Skin and Cancer Hospital. The history of the case is as follows: Twelve years ago a small nodule developed upon the ala nasi, which ulcerated and was removed but soon recurred. In the last ten years the lesion has been treated by almost every plan short of complete ablation of the nose, but always with prompt recurrence. In the summer of 1900 she consulted Dr. Frank Hartley of New York, who advised a plastic operation, but she declined further operative procedures.

The condition at the time she began treatment with x-rays is indicated in Fig. 4. There was an ulcer occupying almost the entire right ala nasi and spreading down on the cheek; a similar small ulcer was on the left ala, and between the two was an area of scar tissue, the result of previous treatment. The ulcers were typical epitheliomas in appearance, deep, with rolled pearly borders, and fed by numerous dilated capillaries. The disease was evident within the nostrils and the walls of the nostrils were of almost papery thinness. The septum was involved and probably also the nasal bones. The ulcers bled frequently and profusely and were the source of much pain. Altogether the case seemed, both to Dr. Engman and myself, to present as unfavorable conditions for cure as possible.

Judging from the treatment she has had, no one has ever made any other diagnosis than epithelioma, and bearing in mind the ulcers, which were perfectly characteristic, the course of the disease, the age of the patient, and the condition of her skin, which showed at various points patches of senile keratosis, I think that there can not be the slightest uncertainty as to the diagnosis of epithelioma.

She was put under daily exposures to x-rays April 26, 1901. By May 10 the borders of the ulcers were shrinking, some healthy epithelium was beginning to grow out from the edges and the discharge was greatly lessened. By June 5 the ulcer on the left side of the nose was healed with a healthy looking scar. By the middle of June the ulcer on the right side of the nose was reduced to the size of a wheat grain. This lesion, at the point where the ala nasi perforated, was slow to heal and the treatments were carried to the point of producing acute dermatitis, so that by August 8 the exposures were stopped on this account. After stopping the exposures, the dermatitis increased until the exposed surface was denuded of epidermis. This healed

in about ten days and at the same time the last trace of the ulcer on the right side disappeared. Since that date, over six months, the scars have remained in a healthy condition. The condition then and since is shown in Fig. 5. She has had exposures from time to time subsequently with a view to destroying any undiscovered remnants of the disease. As far as can be told there is no disease left. There is still some tenderness and at times there is some bleeding from the inside of the nose. On December 19 I had Prof. T. Melville Hardie of the University of Illinois examine her and he kindly gave me the following report:

The general appearance of the mucous membrane covering the septum and the external wall of the nostril is that characteristic of atrophic rhinitis. The membrane is in nearly every place thinner than normal and there are numerous spots where there is present a slight dried oozing of blood, which follows the removal of the crusts of dried mucus. This condition is more obvious in the right nostril, but this is the case partly because of the partial obstruction in the left nostril caused by a deflection and ridge of the septum.

The right inferior turbinated bone is smaller than normal, the atrophy having extended to the bone, besides affecting the mucous membrane covering it. The anterior end of the middle turbinated body is enlarged and the mucous membrane covering it is atrophic. Careful examination disclosed no ulceration in the nostril and no infiltration, the only irregular feature of the diseased portion being the over-red color of the mucous membrane of the floor and the inferior turbinated body. The naso-pharynx also exhibits atrophy of its mucous membrane and bleeds when the crusts of dried mucus are forcibly disturbed.

As far as can be judged, therefore, both from the internal as well as the external conditions, this case is free from carcinoma.

CASE 7.—Patient is a healthy man, aged 38. A year ago an indurated nodule appeared on his nose at the site of a previous wart, which ulcerated and spread rapidly. In May, 1901, he came to my clinic at the College of Physicians and Surgeons. The condition at that time is shown in Fig. 6. There was an ulcer involving the tip of the nose the size of a 5-cent piece. Sections taken from the borders of the ulcer confirm the diagnosis of epithelioma. Fig. 7. It was an epithelioma beginning deep in the subcutaneous tissue, showing many pearls and of rapid growth.

He was put under x-ray treatment on May 23 and was given exposures more or less regularly for two and a half months. There was a healthy scar by September 15. His condition since that time is shown in the accompanying photograph, Fig. 8.

CASE 8.—Healthy man, aged 72, was referred to me Nov. 5, 1901, from the Illinois Eye and Ear Infirmary, for treatment of the ulcer shown in Fig. 9. This was a sharply punched-out ulcer in the right nasal furrow the size of a little finger nail, with raised, waxy borders, profuse blood supply, and painful. The disease began about two years ago in a warty growth which bled easily. In July of this year it ulcerated and assumed its present condition. I got no section of it, but it was in appearance a typical epithelioma and I believe there is no doubt of the diagnosis. The result is shown in the second photograph, Fig. 10. There is a smooth, soft, white, healthy-looking scar, without induration.

CASE 9.—Man, aged 75 years, was referred to me by Dr. Norval H. Pierce, surgeon to Illinois Eye and Ear Infirmary, on Nov. 5, 1901. About eleven years ago a small growth developed on the inner surface of the auricle near the meatus. This gradually became larger and during the past two years has been the source of considerable pain. He made no effort at treatment until the summer of 1900, when he went to the Illinois Eye and Ear Infirmary. The ulcer was there recognized as an epithelioma and during the summers of 1900 and 1901 he was treated at the Infirmary, whence he was referred to me by Dr. Pierce. The sections taken at the Infirmary

were examined by Dr. E. V. Brown, pathologist to the Infirmary, who made the diagnosis of epithelioma.

When the patient came for *x*-ray exposures there was an epithelioma which involved the circumference of the auditory canal for its external one-third inch and the entire inner surface of the concha, and had spread for half an inch upon the cheek in front of the ear, the tragus having been entirely destroyed. In the last few months it had gotten worse rapidly. He was put under *x*-ray exposures November 5 and given them daily to Dec. 5, 1901, when some erythema developed and the ulcer began to heal. The sittings were nevertheless continued to Jan. 25, 1902, when there developed marked congestion of the exposed area. This has gradually subsided and with its subsidence the ulcer healed. Until a few days ago there remained an ulcer about half the size of a little finger nail. This has healed and the entire site of the epithelioma is now covered by healthy skin. Were the tragus not missing it would be hard to discover that an ulcer had existed. That side of his head has been entirely free from sensitiveness or pain since about two weeks after beginning treatment.

CASE 10.—Mrs. W., aged 61, was referred to me by Dr. M. F. Engman of St. Louis. About twelve years ago a lesion developed on her forehead above the right eye which was recognized as an epithelioma. Two years ago it had developed into an ulcer the size of a half dollar and in November, 1899, she went to Dr. William T. Bull of New York City. Dr. Bull has kindly given me his memoranda of the case as follows: "Circular ulcer of forehead in center and reaching to eyebrows and as large as a 50-cent piece. Edges slightly elevated and hard—movable. This appeared first ten years ago as an indurated nodule and was destroyed by caustics. It reappeared and was cut out three times—the last time four years ago. At operation (Dr. Bull's) the ulcer with a wide margin of skin was removed and the raw surface covered with four skin grafts. Healing was complete in three weeks. Dr. Dunton (33 East 33d St.) examined the tissue removed and pronounced the growth an epithelioma." After Dr. Bull's operation the scar remained healthy until September, 1901, when two small ulcers developed in the border of the scar.

The condition when she came under my care Nov. 14, 1901, is shown in the accompanying photograph, Fig. 11. On the forehead above the left eyebrow there is a white, healthy-looking scar 2x2 inches, which is not movable. On the external border of the scar there were two small ulcers, one at the upper outer angle the size of a little-finger nail, the other at the lower outer angle somewhat smaller. Both had raised, hard, pearly borders, had numerous dilated capillaries around them, and presented the picture of typical small epitheliomas. The upper half of the inner border of the scar was occupied by a red, indurated, scaly patch an inch long by half an inch broad, around which were numerous dilated capillaries. This presented the picture of an inflamed patch of senile keratosis undergoing degeneration into epithelioma.

She was given exposures daily over this patch and over the ulcers until the lesions became somewhat inflamed, and afterwards the dermatitis was kept at this stage. By Dec. 8, 1901—approximately a month—the ulcers were healed and by January 8—two months—the induration had entirely disappeared. The skin was smooth, but quite red from *x*-ray effects. The condition since that date is shown in Fig. 12. The skin at the site of the ulcers is smooth, perfectly soft, and free from induration. The site of the patch of verruca senilis on the inner border of the scar is still slightly red as a result of the exposures, but it is smooth and soft and the induration has entirely disappeared.

CASE 11.—Lady, aged 50 years, was referred to me by her husband, who is a physician. Five years ago the disease began as an indurated tubercle near the inner canthus of the left eye. Its condition, when she began treatment, is shown in the accompanying photograph, Fig. 13. The disease involved an area on the side of the nose and around the inner canthus as large as a 50-cent piece. There were two ulcers in the area, one the size of a fingernail on the side of the nose, the other half that size at the inner canthus. The ulcers were sharply excavated, with elevated rolled nodular bor-

ders and around them the tissue was indurated and waxy-looking. It was a typical small rodent ulcer such as is often seen in this location, but no tissue was gotten for examination. The result after two months of treatment is shown in Fig. 14. There is practically no scarring; the skin is white and smooth and there is no induration. It would be hard to say that any ulcer had existed. The case illustrates the ease with which lesion about the eye can be treated with *x*-rays.

CASE 12.—Spare-built man, aged 35, was referred to me by Dr. T. J. Knudson from St. Luke's Hospital. Eleven years ago a small nodule appeared on the right cheek below the eye, which gradually increased in size and after two years ulcerated. The lesion was treated from time to time by different surgeons in various parts of the United States. Four years ago he was admitted to Cook County Hospital in the service of Dr. T. A. Davis. Dr. Davis did a radical operation, removing the ulcer and a large amount of the surrounding tissue and restoring the lower lid by an extensive plastic operation. At the end of a year the disease recurred in the scar and rapidly enlarged, involving the orbit. Last winter he was in Cook County Hospital in the service of Dr. Charles Adams. The disease had then attained such an extent that a radical operation was not undertaken. He recently went to St. Luke's Hospital, whence after a few weeks' attention he was referred to me by Dr. Knudson.

When he came to me the disease involved the entire orbit, the upper and lower lids, the side of the nose and the cheek. A shrunken atrophic globe remained, which was retracted deep in the orbit. Before undertaking treatment by *x*-rays I had Dr. W. H. Wilder see him and at my request Dr. Wilder removed the eye on December 5. No attempt was made to destroy the carcinoma in this operation and on December 14 he returned for *x*-ray exposures. The accompanying photograph, Fig. 15, does not adequately show the condition at that time. A photo-micrograph of a section of the tissue taken from the lower lid is shown in Fig. 16 and confirms the diagnosis of epithelioma. At this time the patient was suffering exquisite pain, which had not been relieved by removing the eye, and from anxiety, pain and loss of sleep his physical condition was greatly reduced.

He was put under *x*-ray treatment December 14 and had almost daily sittings to January 27. The exposures were carried to the point of producing erythema and slight desquamation, but no weeping. Within a week after beginning the treatment his pain had ceased and the discharge began to diminish. Since that time the improvement has been continuous. The borders and the nodules have gradually shrunken and the ulcer has become smaller, until the lesion remaining bears no longer any resemblance to epithelioma. The small surface still not covered by epidermis has the appearance of a healthy granulating wound. All surrounding tissue is smooth, soft, freely movable, free from induration, and almost unscarred. The present condition is shown in Fig. 17. There was so much superficial destruction of tissue that the formation of epidermis has not taken place over the entire surface. As shown in the photograph there is still an area on the inner side of the orbit about the size of a dime which is uncovered by epidermis, but is still diminishing in size. The patient has been free from pain practically since the beginning of the treatment, and has entirely regained his health and spirits.

It is interesting to compare sections of tissue taken before the disease was put under *x*-ray treatment with sections taken while the tumor was subsiding. Figure 16 is a section from the border of the ulcer before the treatment was begun; it shows abundant infiltration of embryonic epithelium. Figure 18 shows a section taken from the same location when the tumor was subsiding. The carcinomatous masses are now replaced by a degenerated waxy substance without structure and staining a faint blue with hematoxylin. The contour of the epithelial cells has been lost and the cell nuclei have disappeared. There is evidently a degenerative process of some sort going on, but what it is can not be said.

The above is a list of consecutive cases of epithelioma and I believe all of them can be claimed as successful.

That there will not be recurrences time alone can show, but from the character of the scars I am willing to hazard the opinion that these cases will not show an unusual proportion of recurrences. If recurrences do take place *in situ* there is every reason to believe that their management would not be troublesome. I do not believe any other method of treatment can show such results in epithelioma as some of the above. Take for example Case 6 and Case 12; the results are unique. Case 12 was beyond relief by any other method. That the ulcer in his orbit should have filled up and healed over with healthy skin would not be regarded as possible were the patient not demonstrable. Such a result in such a case is, I believe, entirely unique.

My experience in epitheliomas is such as to give me great confidence in the method. I have had no case thus far in which the disease failed to yield and usually yield promptly. The scars are soft, free from induration, smooth, and of the color of the normal skin or white, and absolutely healthy looking; indeed, there is almost no scarring.

#### CARCINOMAS OF THE BREAST.

CASE 13.—Mrs. K., aged 48, six years ago, had an operation by Prof. E. C. Dudley of Northwestern University for laceration of the cervix, and her general health has been bad for several years, with complete nervous break-down, but without demonstrable lesion. In 1899 a tumor developed in her right breast, which was recognized as a carcinoma and in April, 1900, was removed. Recurrence became evident in the scar six months after removal, in the fall of 1900. Eight months later, in July, 1901, she began *x*-ray exposures; in the mean time, in the spring of 1901, she had been seen by Prof. Christian Fenger and the case pronounced inoperable. The condition when she came to me is shown in the accompanying photograph, Fig. 19. The skin and subcutaneous tissue for an area six inches in diameter around the center of the scar was dense, hard, and waxy-looking and infiltrated with carcinoma. In and around the center of the scar there was a group of waxy-looking nodules which were for the most part denuded of epidermis and at points ulcerating. The arm was greatly swollen and tensely edematous down to the fingers.

The case was put under daily *x*-ray exposures July 18, 1901, and by August 15 marked dermatitis had been caused over the entire exposed area, and a bulla had formed over the center of the tumor. The treatment had been as vigorous as I dared because it seemed evident if anything was done it had to be done quickly. This effect disappeared by September 2, when the entire surface had become covered with epidermis. At the same time there was a very marked shrinking in the nodules, and the edema entirely disappeared from the arm. With the exception of an interval of six weeks, when she was acutely ill, the patient has had treatment regularly from September to date. An acute dermatitis was again set up in the latter part of October, but since that time the exposures have not been carried to the point of producing an acute effect. On November 8 I made the following note: "The dermatitis has entirely disappeared; the skin is of normal color except for some pigmentation around the periphery of the exposed area. The tissue, where the tumor existed, is smooth and it is impossible at present to find any evidence of carcinoma in this area. All of the nodules have entirely disappeared." The chest wall has remained in this condition since November 8. The condition at the present time is shown in the accompanying photograph, Fig. 20, for which I am indebted to an amateur photographer. As far as her attending physician, who is an ex-interne of Cook County Hospital, and I can ascertain there is no evidence of carcinoma left in the breast or shoulder. There has been no return of the edema to the arm. The right arm is slightly larger than the left, but there is no pitting on pressure and it is not in the slightest degree edematous. The increase in size is, I believe, a permanent connective tissue hyperplasia, due to the long-continued lymphatic obstruction and analogous therefore to

an elephantiasis. The disappearance of the edema in this case is, of course, a highly instructive fact. This patient is not in good health, but what the character of her present trouble is, first-class men are unable to decide. Her present condition is in no way directly connected with her breast trouble and it can not be traced to any metastasis.

CASE 14.—Mrs. C., aged 58, was referred to me by Dr. C. C. Gratiot of Shullsburg, Wis. The patient was in Dr. Christian Fenger's care in Passavant Hospital in July and August, 1900, and the following facts are taken from the hospital record, which Dr. Fenger kindly placed at my disposal: "Her present (July, 1900) trouble began about six years ago when patient noticed a little hard lump on the inferior aspect of the left breast on the axillary side. There was a scarcely perceptible enlargement of the hard area until about two years ago when the patient noticed a more rapid enlargement. She then consulted Dr. Sheldon of Madison, Wis. At that time this growth developed very fast and broke through the skin and formed an open sore, which grew in dimensions until it is now the size of a silver dollar. Dr. Sheldon advised an operation, whereupon she consulted Dr. Fenger." Dr. Fenger removed the breast with the axillary and supraclavicular glands in July, 1900. A few months after removal the disease reappeared in the scar. She returned to Dr. Fenger last summer, but he found the case beyond operation. The condition when she came to me November 1 is shown in the accompanying photograph, Fig. 21. As seen in the illustration, there was a mass of carcinomatous tissue on the left side involving an area of about a square foot. The nodules varied in size from a hazel-nut to the size of a small apple. At the upper inner angle there were a couple of ulcers  $2\frac{1}{2}$  to 3 inches in diameter. Around the main mass and separated from it by distances of from two to three inches or more, were numerous nodules the size of a hazel-nut. She had on two occasions suffered alarming hemorrhage from the surface. Dr. Fenger had thoroughly removed the glands in the axilla and above the clavicle and no enlarged glands in either of these locations were found. When she began treatment she was suffering a great deal of pain. She was so weak that a nurse had to bring her by easy stages from the nearest hotel for her treatments and she was in every way thoroughly haggard and worn.

She was put under *x*-ray exposures on November 1 and the sittings were given daily for two months and every other day or less frequently after that. Two weeks after the treatments were begun she volunteered the statement that her pain was gone; and she has had none since. On January 17 I made the following note: "There has been rapid subsidence of the tumor going on for the last month. The improvement can be seen from week to week. There is at present only a slight superficial ulceration at one point about the size of a dime and one small nodule the size of a pea. The surface is free from infiltration and thickening and the redness has almost disappeared. The skin is considerably pigmented." Improvement has continued since that time. The condition at the present time is indicated in the accompanying photograph, Fig. 22. There is no evidence of carcinoma left on the chest wall. There is a thin, soft, brownish-white scar which is almost freely movable. Around the borders of the scar there are numerous dilated capillaries, the remnants of the previous abundant blood supply going to the tumor. It seems hardly credible that this scar represents the site of the previous tumor.

Her general condition has progressed equally well. As I said above, she has been free from pain since ten days after treatment was begun. Since January 1, she has been strong enough to come in alone three times a week for her treatments from a town thirty-five miles from Chicago. She has regained her appetite and has increased in flesh decidedly (10 to 15 pounds). Now she presents the picture of a healthy old lady.

CASE 15.—Miss X., aged 49, was referred to me by Dr. A. J. Ochsner. In February, 1899, she noticed a hard lump in the left breast, which was followed by gradual retraction of the nipple. In February, 1900, the breast was removed

by a prominent surgeon. The disease soon recurred in the scar and in October, 1901, a second operation was done, after which the wound healed but soon broke down in two ulcers; then she consulted Dr. Ochsner, who referred her to me. When she began treatment with x-rays there were two ulcers in the scar each the size of a 25-cent piece, surrounded by indurated tissue. The case was put under x-ray exposures on November 25 and by January 7 had had twenty exposures when considerable erythema developed, and exposures were stopped for two weeks. Since that time she has had exposures every other day or at longer intervals to date, with the maintenance of pigmentation and very slight irritation. With the first development of dermatitis the ulcers rapidly grew smaller and by January 20 had entirely disappeared along with the induration. Since that time the scar has been soft and free from all evidence of carcinoma. Within a month she has been examined by Dr. Ochsner, who found no evidence of carcinoma remaining. This case had had two operations and practically no further hope from operation remained. Its rapid improvement under x-rays illustrates the advantages of getting hold of these recurrent cases early.

I have treated three cases of carcinoma of the breast without getting rid of the local trouble. Two of these, however, were under treatment less than six weeks, so that the method did not have a fair trial. These cases were as follows:

CASE 16.—Mrs. R., aged 38, had a very extensive recurrent carcinoma of the breast. The case had been passed upon as inoperable by Dr. Charles McBurney of New York. This was the first case of this sort that I treated and the chances of benefit seemed to me then so infinitesimal that with my concurrence treatment was discontinued after five weeks. There was no positive effect.

CASE 17.—Mrs. W., aged 65, with inoperable carcinoma of the breast, was referred to me by Dr. A. J. Ochsner. This patient was under treatment for a month without apparent effect and quit.

CASE 18.—The third case must be put down as a failure. Mrs. J., aged 50, with recurrent carcinoma of the breast, was referred to me by Dr. J. H. Hoelscher. There was a thick mass of carcinomatous tissue, four inches in diameter, ulcerating at the center and attached to the ribs at the location of the nipple. The supraclavicular glands were enlarged. This patient was under treatment from Sept. 3 to Jan. 24, 1902, having in all 66 sittings. Only once was the treatment carried to the point of producing acute dermatitis. There was no apparent effect on the disease and she died suddenly in January from involvement of the lung. This case looked like a favorable one as far as getting rid of the local disease was concerned. Why I failed in this I have not satisfactorily explained to myself. It was a typical scirrhus of the breast. It is unquestionable that there is a difference in individuals in their susceptibility to x-rays. This is seen in the reaction of healthy as well as diseased tissues. I have seen it displayed in different forms of carcinoma, although the above case and perhaps Case 20 are the only ones of my cases in which x-rays have failed to produce a positive effect after sufficient exposure.

#### DEEP-SEATED CARCINOMAS OF NECK AND HEAD.

CASE 19.—Man, aged 68, was referred to me by Prof. R. R. Campbell, of the Chicago Polyclinic. In the spring of 1901 he had an epithelioma removed from the lower lip, with rapid recurrence in the glands of the lower jaw and neck. A radical operation was done in June, which was followed by a rapid recurrence of the disease in the supraclavicular glands. Dr. J. B. Murphy and Dr. Christian Fenger saw the patient in

September and he was told that there was no further hope from operative procedures.

When he began x-ray treatment there were tumors on either side of the neck above the inner third of the clavicle as large as an egg and the surrounding tissue was infiltrated with carcinoma. He was put under x-ray exposures on September 26 and kept under daily sittings with a few intervals, the longest being ten days, for three months. Within a month after the exposures were begun and at the time that dermatitis was produced there was very marked subsidence of the tumors; they disappeared almost entirely and remained in this condition for six weeks. After an interval of nearly three months the case was seen again by Dr. Murphy on December 3. He gave me his opinion at that time that the tumors had not only been checked in growth, but that they were very markedly smaller than when he had seen them three months before. Soon after this, however, they began to grow rapidly and the patient would undoubtedly have died very promptly from carcinoma had he not been taken off by an intercurrent malady.

In this case we were hampered by the fact that tissue transposed in the plastic operation, which was very extensive, was quite sensitive to the x-rays and the patient was unwilling to have the full effect of the rays produced.

I have under treatment at the present time two very similar cases. Case 20, man, aged 55, was referred to me by Dr. L. L. McArthur, Surgeon to St. Luke's Hospital. This is a case of rapid recurrent carcinoma of the neck after removal of carcinoma of the tongue. The case has been under treatment since November 25 and has grown worse. For three weeks in January the treatments had to be omitted and during that time the tumor developed very much more rapidly than before. The exposures were renewed on February 3 and have been given vigorously since that time. That the disease will be checked seems altogether improbable.

CASE 21.—Man, aged 60, is a case very similar in its history to Case 19. This patient was operated on by Dr. Butlin of London and later by Dr. Maurice Richardson of Boston. In order that he might be nearer his home he was referred to me Jan. 18, 1902, by Dr. Richardson and Dr. F. V. Williams, who had been giving him x-ray exposures. In this case the floor of the mouth, the neck and the lower jaw were riddled with carcinoma and the patient's condition has been regarded as perfectly hopeless. This patient had exposures as strong as I dared give them and a dermatitis was quickly produced. This patient died March 10 from exhaustion. At the time of his death all of the nodules in the neck had disappeared and some healing of the sinuses had taken place. Altogether, the subsidence of the carcinomatous tissue had been remarkable.

CASE 22.—Man, aged 71, was referred to me by Dr. A. J. Ochsner, with a rapidly growing carcinoma the size of a fist, involving the right angle of the lower jaw. This patient continued under treatment a month and quit after there had been produced considerable softening of the tumor. There seemed good grounds for hoping to reduce this tumor had the treatment been continued.

CASE 23.—Man, aged 64, referred to me by Dr. George F. Bradley. In January, 1901, an epithelioma was removed from the lower lip by a V-shaped incision. In June, 1901, Prof. N. Senn of Rush Medical College did a radical operation, removing part of the lip and the glands beneath the jaw. About six weeks before he came to me the disease recurred and at the time I saw him there was a tumor occupying the whole area under the chin as large as a small apple, with an ulcer in the center almost two inches in diameter and easily an inch deep. There were numerous enlarged glands at both sides of the neck. He was seen by Dr. A. J. Ochsner, who advised the use of x-rays.

The patient has been under treatment since October 24. There was for a while great improvement in the case. The ulcer under the chin was reduced to the size of a hazel-nut, but lately the patient has been going backward and most of the improvement has been lost.

CASE 24.—Man, aged 70, was referred to me by Dr. William H. Wilder, with extensive carcinoma involving all the struc-

tures in and around the orbit of the right eye. The growth had progressed within the cranium when the treatment was begun. The treatment in this case continued two months with decided amelioration in his condition for a while, both as regards the appearance of the growth and his pain, but later evidences of rapid intracranial growth appeared and the treatments were discontinued.

Looking back at this case it is Dr. Wilder's opinion and mine that we should have taken out enough of the bone of the orbit to have laid bare the structures beneath, so that the *x*-rays could have been thrown directly on the intracranial growth. Dr. Wilder suggested to me that had this been done there might have been a chance of controlling the disease, so marked was the effect upon the diseased tissue which was directly exposed.

#### CARCINOMAS IN THE ABDOMINAL CAVITY.

CASES 25 to 29.—I have had under treatment five inoperable cases of carcinoma in the abdominal cavity; one from Dr. A. J. Ochsner, two from Dr. Christian Fenger, one from Dr. Fernand Henrotin of Chicago, and one from Dr. M. DeWitt Pollock of Decatur, Ill. Two of them died within a week, and one six weeks after beginning treatment. One of them has just died three months after beginning treatment. The fifth case is still under treatment four months after it was begun, but will probably soon die. All of these cases were of the most desperate character when treatment was begun, and in the opinion of the physicians who watched them there has been some reason to think that they have been more comfortable under the exposures and that the pain has been decidedly relieved. But the course of cases of this sort is sufficiently uncertain to interfere with any definite claims of benefit in so small an experience.

There is little ground for hoping that the *x*-rays, as they must be applied at present, have more than a slight effect on malignant growths situated in the cavities of the body. There is some reason to believe that the use of *x*-rays in such cases has an effect in relieving pain. And as *x*-ray exposures may be given these patients without disturbing them or interfering with their comfort there seems no reason why they should not have the benefit of the remotest chance of relief.

#### SARCOMA.

CASE 30.—Man, aged 24, was referred to me by Dr. A. J. Ochsner on Sept. 2, 1901. This case was reported in detail.<sup>3</sup> Briefly, his history is that in February, 1901, he noticed a hard swelling below the angle of the jaw on the left side of the neck which gradually increased in size, and in May, 1901, he noticed a similar hard swelling on the right side of the neck which rapidly increased in size. In August, 1901, he consulted Dr. Ochsner, at which time there were large immovable diffuse swellings on either side of the neck, the size of a man's fist. Dr. Ochsner made a diagnosis of sarcoma and on August 19 removed the tumor on the left side of the neck. On September 2 he sent him to me for exposures to *x*-rays. At the time there was a healthy scar on the left side of the neck and a large swelling on the right side, as indicated in the accompanying photograph, Fig. 23. It was hard, diffuse, not movable, and the neck was almost rigid from interference with motion. Under a month's *x*-ray exposures this entirely disappeared, the result being shown in Fig. 24. Since that time the man has gained 12 pounds in weight and on November 1 wrote me that he had gone back to his work. There was no evidence of recurrence up to March 1—five months—but on March 10 he writes me that some swelling is returning. I wanted to have him for further treatments after the first month, but he was unable to stay in the city.

I have been extremely anxious to have him for further treatment, but thus far he has been unable to return.

As to the diagnosis in this case, Dr. F. R. Zeit, professor of bacteriology and associate professor of pathology in Northwestern University has kindly given me the following report:

"My diagnosis of small round-cell sarcoma is based upon: 1. The histo-pathology of the tumor—small round-cells, somewhat larger than red blood corpuscles, densely packed together, traversed by blood channels without walls and the almost entire absence of stroma or connective tissue framework; and 2, the clinical description of Dr. Ochsner—a large diffuse, infiltrating and proliferating rapidly growing tumor in the neck, no inflammation, and which at no time was circumscribed or movable. No enlargement of other glands. I think this effectually excludes all simple hyperplasias, lymphadenoma, lymphatic leukemia, Hodgkin's disease (pseudo-leukemia). This tumor was not produced by a progressive development of lymphadenoma from gland to gland, but started, no doubt, from one gland and infiltrated by proliferation the surrounding structures at once."

CASE 31.—Man, aged 67, osteosarcoma of the right shoulder, with symptoms of sarcoma of the bladder. There was profound cachexia and evidences of general sarcomatosis. The patient was put under *x*-ray exposures, chiefly with the hope of relieving his pain. He was given 16 exposures without effect upon the tumor, but according to his voluntary statement with considerable relief from pain. With my approval the treatment was discontinued.

CASE 32.—Woman, aged 60, with extensive inoperable sarcoma involving the right pectoral muscles and shoulder. She had treatment for a month with marked relief from pain according to her voluntary statement and in the opinion of her physician, Dr. William Fuller, but without further effect.

#### GRANULOMA OF UNCERTAIN CHARACTER.

CASE 33.—Man, aged 57, was referred to me by Dr. A. J. Ochsner. The diagnosis in this case was not positive. The patient came to Augustana Hospital in Dr. Ochsner's service, Oct. 20, 1901, when the following history was taken: "Two months ago a carbuncle developed on the right cheek. The whole right side of face became painful and swollen; this subsided and three weeks ago the patient noticed a small soft swelling at site of carbuncle. This has increased to present size. It has been opened three times, discharging blood and serum. No tenderness or pain is present. Present condition: Right cheek is slightly reddened and indurated. Downward and forward from malar bone a softish swelling with few crusts, 2.5 cm. in vertical diameter and 2 cm. in horizontal diameter. On pressure discharges sero-purulent fluid. Mucous membrane on inner surface opposite tumor smooth." General health is good; a well-nourished healthy man.

Dr. Ochsner removed the entire mass, going well out beyond the diseased tissue, and closed the wound. The wound remained clean but failed to heal and the tissue around began to break down and within two weeks there was an unhealthy ulcer with a cavity the size of an olive surrounded by bluish flabby tissue.

The pathologic findings were not definite. It was a granuloma with numerous giant-cells, but its character was not definitely determined.

The case was then, November 2, put under daily *x*-ray exposures and practically no attention paid to the local dressing. In two weeks some dermatitis was produced and the ulcer began rapidly to fill up. In three weeks it was healed with a perfectly healthy scar and has remained well to date.

#### KELOID.

CASE 34.—Boy, aged 10 years, was referred to me by Prof. D. A. K. Steele of the University of Illinois. The patient had a keloid form in his vaccination scar and another keloid form upon a scar on the helix of his right ear. They were removed and promptly recurred. The keloid on the arm was a typical keloid, as will be seen in the accompanying photograph, Fig. 25. It was 2½ inches long, three-quarters of an inch broad and one-half inch high. Each of the stitch scars showed

3. JOUR. A. M. A., Jan. 18, 1902.

a keloid about the size of a marrow-fat pea. The keloid on the ear was a curious-looking globular tumor an inch in diameter, purplish in color, with dilated blood vessels coursing over it and had grown rapidly. It bore in appearance a resemblance to a sarcoma.

The keloid on the arm was put under *x*-ray exposures in December, 1900, and proved entirely rebellious to daily sittings for a long time. It was not until after 80 sittings that any effect was produced. Then I carried the treatment to the point of producing a very acute dermatitis, which was followed by the formation of a superficial necrotic membrane. This healed over in three weeks and after that time (September, 1901) the keloid rapidly shrank. It had practically disappeared by Nov. 1, 1901. The condition since that time is shown in Fig. 26. The entire keloid has disappeared, except for a slight ridge down the center of the scar. I think that this has perhaps increased slightly since the exposures were omitted in November, so that I do not believe a successful result can yet be claimed.

It was interesting to note the sharp limitation to the keloid of the acute inflammatory process produced by the *x*-rays. There was erythema in the exposed normal skin surrounding it, but this disappeared much more rapidly than the inflammatory process in the keloid. The disappearance of this

There seems, therefore, to be some reason to hope that the method may be of use in attacking scars.

#### PSEUDO-LEUKEMIA.

CASE 35.—Boy, aged 4, was referred to by Dr. A. J. Ochsner. This patient was in the Presbyterian Hospital in May, 1901, in Dr. Fenger's care, and I am indebted to him for the hospital record from which the following facts are taken: The family and personal history prior to the development of the present trouble are without significance. The present trouble began in December, 1900, as small hard swellings below either ear. The mother stated that every two or three days she could see more of the swellings appear. The swellings were symmetrical for about three months, when the right side grew larger. May 20, 1901, when the patient entered the Presbyterian Hospital, the following notes were made:

"Submaxillary, cervical, and supraclavicular lymph glands are enlarged, hard, discrete. There are tense swellings both anteriorly and posteriorly, especially on the left side of the neck. No other enlarged lymph glands found." The blood examination showed 4,200,000 reds and 10,000 whites; hemoglobin 50 per cent.

Dr. Fenger dissected out two lymph glands in the neck and the "pathologist's report states that there is no evidence of tuberculosis in the gland and that the histology coincides

Fig. 27.—Case 35. Hodgkin's disease, Sept. 11, 1901.

loid was due to absorption and not to necrosis. The only ulceration that appeared was the superficial membrane not thicker than parchment, but a mass of tissue disappeared about one-half inch in thickness.

In July, 1901, the treatment was applied to the tumor over the ear and after 16 sittings (August 10) was carried to the point of producing dermatitis. After the development of the dermatitis there was a very perceptible shrinking in the size of the tumor. The treatment was neglected by the patient until December, 1901, and since that time has been taken up in a desultory way. The growth has decreased very decidedly since the treatments were renewed, but there is still a tumor left about half the original size.

Keloids are scar tissue of such marked vitality that it would be expected *a priori* that they would not be affected by *x*-rays except by producing a reaction that would destroy any healthy tissue. Yet this keloid was certainly made to disappear without necrosis and without affecting the normal connective tissue. It was found in my first case of lupus that there was a great thinning and softening of the scar tissue in the neck, and this observation is a confirmation of that of other workers.

Fig. 28.—Case 35. Since Nov. 1, 1901.

with that of a pseudo-leukemia." The diagnosis of Hodgkin's disease was made and "the patient discharged with a statement to parent that little if anything can be done to relieve patient." In August, 1901, patient entered Augustana Hospital in Dr. Ochsner's service. The condition of the swellings at that time is indicated in the following note: "A large irregular swelling on the right side of the neck, size of a small fist, extending from below and behind the right ear to the clavicle. Numerous hard masses varying in size from a filbert to an English walnut can be felt. Small swelling of the left side of the neck about half the size of that on the right. The swellings are not tender, painful or red and are freely movable. No enlargement of liver or spleen." The diagnosis of Hodgkin's disease was made and Dr. Ochsner dissected out a large mass of glands on the right side of the neck.

On September 11 he referred the case to me for exposures to *x*-rays. The condition is shown in Fig. 27. There was a healthy scar on the right side of the neck and on the left side a swelling the size of a fist, made up of a group of greatly enlarged glands. They were hard, painless, and freely movable. These glands were put under exposures to the rays on September 11. In the course of a month, erythema

was produced and the glands rapidly diminished in size. At the end of two months there remained three or four small glands on this side of the neck which were quite soft and not larger than a filbert. Almost all the swelling had disappeared and the slight swelling that remained was as soft as adipose tissue. The case has been under desultory treatment from that time to this without change. The condition at the present time is shown in the accompanying photograph, Fig. 28. The general physical and mental condition of the patient has improved very greatly. The number of red and white corpuscles are about the same as when the blood was examined May last; there is now 80 per cent. hemoglobin as against 50 per cent. in May.

CASE 36.—Man, aged 50, was referred to me by Dr. L. L. McArthur. The patient had typhoid fever six years ago, but aside from that has had no serious illness since childhood. In childhood he had an attack of inflammatory rheumatism; otherwise, his personal and family history are negative.

In April, 1900, he noticed a swelling under the right arm and another on the inside of the elbow. These gradually increased in size and in October, 1900, he consulted Dr. D. N. Eisendrath, who found in addition enlarged glands in the neck, in the other axilla, in the groins, and along the side of the

the right epitrochlear gland November 19, while he continued the parenchymatous injections of arsenic in the axillary gland. By December 18 I had produced considerable erythema over the elbow and by that time the gland was reduced to less than half its previous size. In the meantime the axillary gland, which was having injections of arsenic, showed no change. These injections were then stopped and at Dr. McArthur's suggestion I began exposures also over the axillary glands. The exposures over the epitrochlear gland were continued and by Jan. 1, 1901, all apparent swelling had disappeared and only a soft gland the size of a filbert was left. By January 7, after fifteen sittings and upon the development of considerable erythema, the axillary gland had become quite soft and very much reduced in size. By January 20, almost all of the axillary swelling had disappeared and the condition has remained the same since that date—Fig. 30. There is very slight puffiness at the site of this tumor, but it is as soft as the softest adipose tissue. The man's general physical condition has been greatly improved. Dr. M. L. Goodkind, who saw the patient after an interval of several months, particularly called my attention to the

Fig. 29.—Case 36. Hodgkin's disease, Dec. 18, 1901.

abdomen. The case was seen in consultation by Dr. Christian Fenger, who agreed with Dr. Eisendrath in the diagnosis of Hodgkin's disease. The diagnosis of Hodgkin's disease was also made by Dr. E. J. Doehring and Dr. M. L. Goodkind. The blood examination made at the time that Dr. Eisendrath saw the case showed 80 per cent. hemoglobin, 5,000,000 red corpuscles, and 10,000 whites.

Previous to beginning treatment with *x*-rays the patient had for a long time been taking arsenic and for several weeks had been having parenchymatous injections of arsenic into the tumors. In spite of this treatment the glands had not decreased. The patient's general health had failed and he showed marked cachexia.

The size of the tumor in the right axilla when *x*-ray treatment began is shown in Fig. 29. It was about as large as a child's head and interfered seriously with the movement of the arm. The right epitrochlear gland was almost as large as a goose egg. Its vertical diameter was four inches; and its transverse diameter about two and a half inches. Both of the glands were movable but densely hard.

At Dr. McArthur's suggestion I began daily exposures over

Fig. 30.—Case 36. Since Jan. 20, 1902.

improvement in his general condition, which he characterizes as astounding.

The first case continued the use of protonuclein and the second arsenic, at the suggestion of their physicians, during most of the time that they had *x*-ray exposures and that mitigates against the conclusiveness of the evidence in favor of the effect of *x*-rays in these cases. The fact remains, however, that in the case of the child the protonuclein had absolutely no effect on the glands before the *x*-ray exposures were begun, and in the case of the man the disease had progressed in spite of the vigorous treatment with arsenic. It is also to be borne in mind that the tumors in pseudo-leukemia disappear spontaneously at times and act in the most erratic manner. Against this we have the fact that in neither of these cases, after a year and a year and a half respectively, had any change shown itself, and no acute disturbance of health of any sort occurred at the time that these cases were under *x*-ray treatment to precipitate

the subsidence of these glands. On the other hand, the sequence of the exposures to *x*-rays and the subsidence of the glands in these cases was as close and direct as it is possible to conceive. In the case of the child the tumor began to subside with the evidence of the accumulation of *x*-ray effects on the tissues. It was the same when the epitrochlear gland in the man was exposed and the unexposed axillary gland showed no change. The same sequence was shown in the axillary gland when it was put under the influence of *x*-rays. In each instance evidence of effect on the gland began to show itself when a corresponding effect on the skin was produced. That the subsidence of the gland might occur spontaneously in one case at identically the same time with the exposures to *x*-rays is a coincident that might happen; that this coincident should happen in two instances in direct succession is in the highest degree improbable; and that the same coincident should happen in the third instance in succession is mathematically practically impossible.

#### LEUKEMIA.

I have exposed one case of splenic leukemia to *x*-rays. This case was a woman, aged 50, referred to me by Dr. A. J. Ochsner. She had an enormous spleen. The blood examination showed 50 per cent. hemoglobin, 3,000,000 reds, and 300,000 whites. She was given *x*-ray exposures over the spleen for a month with no effect whatever. The exposures, however, were not carried to the point of producing any apparent effect on the skin and in my judgment the case shows nothing.

#### CONCLUSION.

As will be seen, I have not to report an unbroken series of successful cases treated with *x*-rays, but I believe the results attained are such as to give encouragement. For it must be borne in mind that the cases I report are of a character that will never allow of an unbroken series of successes. Excepting a few epitheliomas the whole list represents cases which had baffled skilful men or had been passed upon as hopeless by masters of the profession. A more unpromising group of cases could hardly be imagined. That even some of these cases have been controlled or had their progress stayed seems enough. Many of these cases, when they came under treatment, had attained a much more serious character than they had when first recognized as hopeless. When such cases are put under the influence of *x*-rays sooner, is there not good reason to hope for a still better showing?

The cases are presented for what they are worth and each one will give them whatever weight he considers they are entitled to. One important fact I believe may be claimed as established, not only from these cases but from the work of other men, namely, the *x*-rays have a destructive effect upon tissues of low vitality, and this effect can be utilized under suitable conditions to cause the destruction of such tissues without destroying the involved healthy tissue.

My sections show that *x*-rays cause a degeneration of some sort of carcinomatous tissue and a disappearance of this degenerative substance, presumably by absorption. This disappearance of carcinomatous tissue is followed by the formation of firm healthy scar tissue. A similar process presumably occurs in the disappearance of the diseased tissue in tuberculosis, sarcoma, and pseudo-leukemia. However it occurs, the fact stands that growths of embryonic tissue and other tissues of low vitality are made to disappear under the influence of *x*-rays without the destruction of

the involved healthy tissue; and such a fact is pregnant with possibilities.

The advantages of the method are:

1. It is painless.
2. It destroys diseased tissue, but leaves the healthy tissue in its place.
3. It leaves small scars.
4. It can be used in cases where the surrounding healthy tissue can not be sacrificed.
5. Hence, it is available for cases in which ordinary methods involve extensive operations and serious subsequent disfigurement, as, for example, about the eye and nose.
6. It is available in cases in which ordinary methods are impossible because of the amount of destruction of tissue which complete removal would require; in other words, it is applicable to many inoperable cases.
7. It often relieves pain.

As a general proposition the use of *x*-rays should in my opinion be limited to those cases which for any reason it is inadvisable or impossible to treat by ordinary methods. In other words, until our experience with *x*-rays extends over a longer time, their use should be a reserve method of treatment. I particularly wish to make it clear that I do not advise the use of *x*-rays as a substitute for operations in operable malignant growths. As regards cutaneous carcinomas—epitheliomas—I believe no strong objection is to be found to the use of *x*-rays as a primary method of treatment and some advantages are to be urged for it. Every other malignant neoplasm should have the advantage of operation where it is practicable. On the other hand, I believe that with the present evidence of the effect of *x*-rays upon malignant neoplasms we are justified in maintaining the following propositions: 1. In all cases of malignant disease which have been operated on there is reason to urge the subsequent use of *x*-rays as a prophylactic measure. 2. In all inoperable cases of malignant disease the use of *x*-rays should be tried. 3. In all such cases there is a probability of relieving pain and a possibility of inhibiting the progress of the disease.

#### A BRIEF REVIEW OF FINSEN'S PHOTOTHERAPY.\*

P. C. CLEMENSEN.

Assistant Demonstrator of Anatomy in the Northwestern University Medical School.  
CHICAGO.

It is now about eight years since Professor Finsen of Copenhagen published the results of his first investigations concerning the action of light upon the skin. The results of his experiments were essentially the same as those obtained by a number of other investigators, notably Widmark of Stockholm, namely, that sunburn or erythema solare is not caused by the heat of the sun, as was formerly believed, but is due to the action of the ultra-violet or so-called chemical rays.

Having convinced himself of the fact that the blue and the ultra-violet rays of light were capable of inciting an inflammation of a healthy unprotected skin, Finsen concluded that it would be of material benefit to exclude these rays in the treatment of certain inflammatory conditions of the skin, for example, variola; since in that disease suppuration and pitting are most marked upon the parts exposed to light. In summing up his papers he suggested therefore, on a purely theoretical

\* Read before Chicago Medical Society, Dec. 4, 1901.

basis, that smallpox cases be treated in red light. A few months later Dr. Svendsen of Bergen, Norway, put this suggestion to a practical test and found it to be not only theoretically, but also empirically correct. This gave rise to Finsen's red light treatment for smallpox and may be considered the beginning of what has come to be known as Finsen's phototherapy.

Finsen himself seems to regard this as an incidental discovery, inasmuch as his great aim was to find the beneficial effects of the chemical rays of light. The following quotation from his article on "The Incitation of Light" can not fail to show how strongly he was convinced of this new therapeutic principle: "This chemical quality of light, which from a theoretical point of view must be placed side by side with the two other forms of energy in the sun's rays, heat and light, is undoubtedly a power of Nature (Naturkraft) which, so far, has not been sufficiently recognized in medicine."<sup>1</sup> The results that he has obtained with these rays, as a curative agent for lupus vulgaris and several other kinds of parasitical skin lesions, are well known. Very little, however, has been published in this country regarding the great amount of research work that has been done during the last two or three years, at Finsen's Medicinske Lysinstitut in Copenhagen. The reasons for this

exposed the flexor surface of his left forearm to strong sunlight for three hours (the skin being painted here and there with India ink, to imitate negro skin). In an experiment some years later he exposed the same skin, covered in part with various objects (as shown in Fig. 1) for twenty minutes to the rays of an 80-ampere electric arc-lamp at a distance of 50 to 75 cm. in such a position that the rays would strike the skin nearly at a right angle. In each case there followed an inflammatory reaction of the skin, which he describes in substance as follows:

"1. The inflammation thus incited differs from any other kind of inflammation of the same extent, inasmuch as it was followed by a marked pigmentation of the skin of several months' duration.

"2. It does not appear at once (as does a burn), but has its maximum in one or two days after exposure.

"3. It appears only on those parts of the skin which have been directly exposed to the light, while heat rays are also capable of acting through the clothing."

When the acute inflammatory reaction (of the first experiment) had subsided, Finsen again exposed the arm to strong sunlight and found that the pigmented skin reacted very faintly, while the white patches of skin, where the India ink had been, reacted just as the normal

Fig. 1.—(After Finsen.) Reproduction of a photograph of Finsen's forearm before exposing it to the rays of the arc lamp. Nearest the elbow is a round piece of quartz; following this are five strips of glass. The one nearest to the quartz is red, the second yellow, the third green, the fourth blue and the fifth ordinary clear glass. Besides these are seen the letters N. F., painted with India ink, and a patch of ordinary salve nearest the wrist.

are clearly stated by Finsen in his bulletin of June, 1900, when he says: "Inasmuch as this work has been done in a place which is outside of the great scientific centers of the world, and as the reports have originally been published in Danish, which, of course, is read by only a few outside of the Scandinavian North, it could hardly be expected that the scientific world at large would as yet be thoroughly acquainted with the details of our work and methods."<sup>2</sup>

In view of this fact, a brief résumé of the recent literature on Finsen's phototherapy may be of interest.

#### PHOTO-CHEMICAL INFLAMMATIONS.

By experiments on the skin of his own forearm, Finsen has demonstrated macroscopically how an inflammation produced by the chemical rays of light differs from that of a burn and from an erythema caused by a simple overheating of the skin. Microscopically, he has shown by experiments upon tadpoles that this photo-chemical inflammation differs from other kinds of inflammation, inasmuch as it brings about a characteristic change in the red blood corpuscles.

To describe the technique of these experiments would require a complete translation of the text. Suffice it to say, therefore, that Finsen, in the first experiment,

Fig. 2.—(After Finsen.) Arm after exposure. Finsen's object with the colored glass strips was to study the inflammatory effects of the different colored light on the skin. In that particular the experiment was a failure, inasmuch as no reaction took place underneath either of the glass strips, the skin remaining perfectly white. It was found on the other hand that the skin beneath the quartz plate was equally as inflamed as the uncovered skin. (The little white spot seen where the quartz was placed is due to the glue.) This convinced Finsen that the chemical rays will pass through quartz unaffected, and ever since then he has used quartz lenses for his electrical condensers.

skin did before. From this he concludes that the pigment of the skin is the principal defence against the inflammatory influence of the actinic rays and goes on to say: "We are undoubtedly right in supposing that this is still the principal reason for the negro's darkness, and for the circumstance that the skin of the various races gets darker the nearer we approach the equator."<sup>3</sup>

Several months after the pigmentation had disappeared from the arm that had been exposed to the 80-ampere lamp, Finsen noticed, upon briskly rubbing the skin, that the parts which had been protected by the salve and glass plates (seen in Fig. 2) remained almost white, while the rest of the skin was markedly flushed. "This can only be explained by assuming that the action of the chemical rays had caused a more or less permanent dilatation of the capillaries and smaller arterioles of the skin,"<sup>4</sup> a fact which he later takes advantage of in his chemical-light baths.

Finsen demonstrated the histology of these actinic inflammations in the following way: He took a tadpole, wrapped its body in wet tissue paper and placed it upon a microscope stage in such a way that he could

flush it with a stream of cold water, 1, to keep it alive, and 2, to counteract the heat. He then directed a stream of concentrated sunlight upon the tadpole's tail, and observed through a microscope the following changes in the capillary circulation:

"1. In about ten minutes the blood current became markedly slow and there were many leucocytes present.

"2. A little later, the blood current was completely obstructed (stasis) by red and white corpuscles and there were many leucocytes outside of the vessels.

"3. A marked change took place in the red blood corpuscles; they lost their characteristic oval shape (of the frog) and became stubby and contracted. This change in the red cells was absolutely constant in every experiment and, by fixing some of the tadpoles in saturated sublimate solution, the same condition could be observed in the cut sections. That this contraction of the red cells was not a death phenomenon was shown by the fact that they did not lose their sharp contour nor give up their hemoglobin—the two phenomena which, according to Cohnheim, take place at the death of the red blood corpuscles."<sup>5</sup>

#### THE EFFECT OF LIGHT UPON MICRO-ORGANISMS

Having determined the harmful effects of the chemical rays of light upon animal tissues, it seems but natural that Finsen should next turn his attention to the influence of these rays upon bacteria. A great deal of this work he assigned to his associates. Dr. Valdemar

Figure 3. (After Finsen.)

Bie, his first assistant, investigated the effect of the different rays of the spectrum upon the development of bacteria and found:

"1. That all the different rays of the spectrum, from the red upwards, hamper the development of micro-organisms. That the red rays alone are capable of killing bacteria has not been shown: any of the other parts of the spectrum are able to do so.

"2. That the ability of the rays of the spectrum to kill bacteria rises somewhat uniformly with the exponent of refraction, as far as the beginning of violet, where a marked rise takes place.

"3. That the effect is therefore chiefly due to the violet and ultra-violet rays."<sup>6</sup>

These results have been obtained with the bacillus prodigiösus and the light of an electric arc-lamp of 35 amperes, 44 to 46 volts. The light was filtered through colored liquid filters and the technique in general was that in use at the Finsen Institute.

Dr. A. L. Larsen has made some very creditable researches in order to determine whether different micro-organisms are equally or differently affected by light. He finds: 1. That different bacteria are differently affected by light and that there is considerable difference in the resistance of even closely related varieties. 2.

That the time which the light requires to kill certain species of bacteria bears no constant relation to that needed to impair their growth."

Dr. Sophus Bang, director of the Finsen laboratories, has lately published an extensive article on the effect of light upon micro-organisms. Dr. Bang states that besides the work done at the Finsen Institute, more than one hundred monographs can be found in the literature pertaining to the bactericidal powers of light, but adds that the results obtained by the different investigators do not compare with the amount of work done. He gives great credit to the work of Downes and Blunt, but has this to say in general: "One gets the impression from most of these researches that they have all been done by more or less skilful bacteriologists, but by very poor physicists."<sup>8</sup>

The errors of most of the former investigators have been that: "1. They have all, with one or two exceptions, used test-tubes for their cultures. (The convex surface of the tube, acting as would a convex lens, has thus caused the light to be refracted unequally throughout the media. 2. The intensity of light used, the amount of chemical rays it contained as well as the distance of the culture from the source of light (when artificial light was used) have in general not been stated

Figure 4. (After Finsen.)

by the older investigators. 3. The use of too weak light; few seem to have thought of the fact that when light is decomposed into its various parts, the source of light must be increased in order to get the same effect."

#### THE RED LIGHT TREATMENT OF SMALLPOX.

I have already mentioned the theory upon which this method of treatment is based. The clinical reports show that, in the hands of those who have used it rightly and most extensively, it has proved to be a new therapeutic agent of considerable value. For a successful application of the treatment, Finsen emphasizes the following points:<sup>9</sup>

"1. The exclusion of the actinic rays must be complete; the windows may be covered with heavy red curtains or, better still, window panes of deep-red glass may be used. At any rate the light should be of the same quality as that used in a photographer's dark room. (Red incandescent globes or a faint candle light can be used, when for convenience more light is required than can be obtained through the windows.

"2. The patient must remain in the red light until

the vesicles are dried up, even the slightest exposure to daylight can bring about suppuration and its sequelæ.

"3. The treatment should be commenced as early as possible (at the beginning of the exanthema), for the nearer the commencement of the suppuration the smaller are the chances of success.

"4. This method does not prevent the use of any other treatment that might be considered necessary. (Symptomatic treatment of the patient should, of course, be carried out as usual.)

"5. Death from variola (especially before the period of suppuration, or from such complications as pneumonia) can, of course, not be prevented by the use of this method.

"6. If the patient be brought under this method of treatment early enough and these rules observed, the results, according to clinical experience, will be that suppuration is prevented, the course of the disease shortened and the patient cured without pitting."

Dr. Svendsen, who was the first to try this method and who used it for eight cases of variola, four of which were in unvaccinated children, describes his results thus:

Figure 5.

"The clinical picture of variola was changed, there was no pustulation, no edema, no secondary fever; the patient passed directly from the vesicular stage into convalescence." Dr. Herman Backmann, who has treated 62 cases of smallpox by Finsen's method, says: "The period of suppuration was short and mild, the vesicles dried up much quicker than usual and left no scars."

Dr. C. Feilberg of Copenhagen has reported 14 cases of variola treated in red light at the Copenhagen smallpox hospital. He states: "It must be admitted that this method of treatment is of no insignificant therapeutic value, inasmuch as it shortens the course of the disease, makes it less painful and saves the patient from various complications consequent to the suppuration. When one has seen severe cases of smallpox—the patient bathed in pus—so that the bed clothing sticks to the body, it will be admitted that variola is one of the most painful diseases. All this seems to be avoided by the use of this method."

The exact number of cases that have been reported in the literature, as treated by this method, I am not able to state, but in 1899 between 140 and 150 cases had been reported.

Fig. 3 shows a temperature tracing of one of Professor Feilberg's cases; it will be seen from this chart that there was no secondary fever.

#### POWER OF THE CHEMICAL RAYS TO PENETRATE TISSUES.

That light is capable not only of penetrating the skin, but also the deeper tissues, can readily be shown by a very simple experiment suggested by Finsen. "Close the eyes and look toward the light, then cover the eyes by the hand and note the difference."<sup>13</sup> The amount of light that penetrates the eyelids is really remarkable, as the light has to penetrate skin, tarsal plate and mucous membrane.

Figure 6. (After Finsen.)

Godneff has shown that the chemical rays of light will penetrate the skin. By means of a trochar, he placed sealed glass tubes containing chlorid of silver beneath the skin of cats and dogs. Some of the animals he left in the dark, while others were exposed to direct sunlight. In the course of an hour he removed the tubes and found that the silver chlorid in the tubes from those animals he had exposed to sunlight was blackened, while it was unchanged in the tubes from those animals left in the dark. (Quoted by Finsen.)

By courtesy of Prof. Finsen.

By sealing strips of aristo paper on one side of a person's ear and then turning a stream of concentrated light upon the other side of the ear, Finsen found, from the blackening of the paper, that the chemical rays were capable of penetrating the tissues of the ear. If, however, the ear over the paper was compressed (between two plates of quartz) it was found that the same light would blacken the aristo paper in about one-tenth of the time. "This shows conclusively that the blood forms the chief barrier to the permeability of the chemical rays" (Finsen).<sup>14</sup> Later he repeated these experiments

by placing a rabbit's ear over a plate-culture of the bacillus prodigiosus. He found that the light would penetrate the rabbit's ear and impair the growth of the germ, while if the ear tissue was made anemic the germ was killed very rapidly.

For these reasons, Finsen uses in his lupus clinic a compressing apparatus for producing local anemia of the parts to be treated by concentrated light. This apparatus is shown in Fig. 5, A, and consists of a plano-convex lens of quartz fastened in a metal ring, the convex surface of the lens being turned toward the skin; radiating from the ring are four arms to which are attached rubber bands, that serve to hold the apparatus in position and to compress it tightly against the skin. For treating the sides of the nose, where this form of the apparatus is impracticable, an oblong form is used.

light (Fig. 4) consists of two concavo-convex glass lenses, fastened in a brass ring in such a way that the concave surfaces of the two lenses face each other, while the space between is filled with a copper sulphate solution. This blue, bi-convex, water lens is suspended on an adjustable metal frame and supported on an iron foot. The two shells of glass about the liquid converge the parallel rays of the sun to a focus, while the copper sulphate solution absorbs most of the heat rays (ultra-red, orange and yellow), but transmit the ultra-violet.

The concentrating apparatus for electric light is more complicated, since the rays from the electric arc-lamp are divergent and not parallel like the rays of the sun. Fig. 5 shows a concentrating apparatus for electric light: it consists of two brass cylinders which are made to telescope into each other, like the barrels of a microscope. In the upper end of the wider cylinder are

#### CONCENTRATION OF LIGHT FOR MEDICAL PURPOSES.

Concentrated light is used by Finsen for the treatment of various maladies, but it is for the successful treatment of lupus vulgaris that he has become known throughout the medical world.

In order that a malady may be treated successfully with concentrated light, it must be local, superficial and bacterial. This is Finsen's law in phototherapy and any skin lesion which he may have treated that does not strictly come within these three requirements is not yet beyond the experimental stage. The light used for this method of treatment must be strong, concentrated and cooled. For this purpose Finsen uses in his lupus clinic two kinds of apparatus, one for sunlight and one for electric light. The apparatus for concentrating sun-

placed two plano-convex quartz lenses, marked in the Figs. 5, 1 and 2; the object of these two lenses is to gather the divergent rays of the electric arc-lamp and make them parallel. The lenses (3 and 4) converge these same rays and bring them into focus at a point situated about 70 cm. outside of lens 4. The chamber between the lenses 3 and 4 is filled with distilled water, which absorbs nearly all the heat rays and acts thus as a cooling medium to the light. The ultra-violet rays on the other hand pass through unaffected and, since these rays have the greatest bactericidal power, it will be seen that the water serves the double purpose of holding back the heat and of giving a pure chemical light. In order to keep the column of distilled water between lenses 3 and 4 from getting hot, this part of the apparatus is sur-

rounded by a water jacket, through which a current of cold water is continually flowing. (Fig. 5, B.B.) This concentrating apparatus is held in position by a steel bar projecting from the support around the lamp, shown in Fig. 5. Lens 1 is exactly 15 cm. from the positive pole of the lamp. The apparatus hangs in such a position that its axis forms an angle of nearly 45 degrees with the direction of the carbon poles of the lamp.

#### TREATMENT BY CONCENTRATED LIGHT.

The patient is best placed upon a table or couch; the compressing apparatus placed over the part to be exposed and the rays from the concentrator directed straight on the compressor. It is necessary to watch and see that the rays strike the compressor at a right angle. The exposure should last from an hour and a quarter to two hours, depending upon the intensity of the light used. The electric lamps used by Finsen are from 50 to 80 amperes and four concentrators are attached to each lamp, as seen in Fig. 6. In this manner an area of skin from the size of a quarter to that of a half dollar is exposed each day until the whole patch has been treated. The skin appears red and swollen after the exposure, but necrosis has never been observed. In the case of lupus vulgaris, the treatment is continued for some time after the last nodule has disappeared in order to guard against recurrences.

Sometimes pyrogallic acid ointment is applied to the skin before treatment is commenced in order to make it soft and easily penetrable to light. Zinc ointment is applied as a soothing dressing to the part after exposure.

The statistics given below are tabulated from Finsen's official report of 1900. It shows in a general way the kinds of diseases that have been treated by concentrated light at the Finsen Institute:

| NAME OF DISEASE.                   | PATIENTS TREATED. | RESULTS.  |
|------------------------------------|-------------------|-----------|
| Lupus vulgaris .....               | 454               | Positive. |
| Lupus erythematosus .....          | 142               | Positive. |
| Alopecia areata .....              | 29                | Positive. |
| Epithelioma cutaneum .....         | 17                | Positive. |
| Acne vulgaris and acne rosacea.... | 15                | Positive. |
| Nevus vascularis planus.....       | 10                | Positive. |
| Tuberculosis cutanea .....         | 7                 | Positive. |
| Trichophytia capitis .....         | 6                 | Positive. |
| Favus .....                        | 2                 | Negative. |
| Seborrhea capitis .....            | 4                 | Negative. |
| Eczema faciei et sycosis.....      | 5                 | Negative. |
| Ulcers luetica .....               | 5                 | Negative. |
| Keloid.....                        | 1                 | Negative. |
| Pigmenta trophica .....            | 2                 | Negative. |

The principal advantages of this method of treatment are: 1. It is painless. 2. It promises reliable results for local, superficial and bacterial skin lesions. 3. It gives excellent cosmetic results. 4. It is absolutely without danger.

The disadvantages are: 1. The long time the patient has to be under treatment. 2. The cost of the apparatus, especially the strong electric current necessary for the lamp. The first disadvantage has practically been removed, since Dr. Sophus Bang has succeeded in constructing an electric arc-lamp, which is extremely rich in ultra-violet rays. The lamp radiates practically no heat and gives very little light; the electrodes of the lamp are made of iron, specially prepared, and are kept from melting by the circulation of cold water inside the tips. With this lamp the exposure, which used to last an hour and a quarter, is reduced to three minutes. Dr. Bang is at present trying to construct a new compressor in which a small lamp is to be inserted and in that manner do away with the cumbersome condensers.

#### FINSSEN'S CHEMICAL LIGHT BATHS.

In the latest bulletin<sup>1</sup> there is given preliminary de-

1. Meddel elser fra Finsens Medicinske Lysinstitut, June, 1900.

scription of the chemical-light baths proposed by Finsen, in order to show how the therapeutic principle of these baths differs from that of the Kellogg electric light baths, now much in vogue in Germany. The latter are nothing more than sweat baths for which the heat is being produced by incandescent electric lamps, instead of by hot air or steam vapors. This diaphoretic effect is all the virtue the originator, Professor Kellogg, attributes to them; but after being imported into Europe (by a layman) it was found desirable to attribute to them some of the chemical effects of light. In connection with these proposed chemical qualities of the Kellogg baths the German proprietors have made use of Finsen's name in a way of which he does not approve.

The following is a translation of Finsen's description of his chemical-light baths:

My light baths are arranged in the following way: I use either sunlight or electric light.

Niels R. Finsen.

The sunbaths consist in letting the patient walk naked in a court of bright sunlight, where everything possible is done to keep the temperature down, so as not to make it a sweat bath. By frequent irrigation of the court with cold water, and, if necessary, by an occasional shower-douche on the skin, one can manage to take a sunbath at moderate temperature.

The electric-light bath consists of a circular room of about 12 meters (40 feet) in diameter, in the center of which hang two powerful electric arc lamps of 100 amperes each. The lamps are suspended about 2 meters above the floor. This large room is subdivided into smaller rooms by partitions radiating from near the center, like spokes in a wheel. In each of these subrooms is found an inclined couch on which the patient lies naked. The temperature in these electric light baths is so low that it is necessary to heat the rooms by other means to keep the patients comfortable. At the same time the chemical effects on the skin from the powerful electric

light is stronger than that of bright sunlight. These baths produce a pleasant prickling and slight sensation of heat on the skin.

In the use of these baths, as well as the sun baths, it is necessary to exercise a certain amount of care, inasmuch as there is a great individual difference of toleration to the chemical rays of light. Certain individuals will, even after a 10-minute exposure, present a decided erythema, while others tolerate the same light for hours, their skin presenting nothing more than a slight redness. The indications for these baths and a further description of them I shall not enter upon now, as it is merely my intention to point out the difference between the kind of electric baths, which in reality are nothing more than sweat baths, and the kind of electric light baths, the object of which is a real chemical-light action.

While Finsen as yet refrains from giving any specific indications for these baths he calls attention to the fact, mentioned under photo-chemical inflammations, that the chemical rays produce a dilatation of the capillaries of the skin. "This dilatation of the capillaries insures a greater blood supply and in consequence a better nourishment of the skin." It has also been shown that the chemical rays are powerful counter-irritants; and inasmuch as we treat many chronic skin diseases with stimulating salves, etc., it would be hard to foretell the future therapeutic uses of these chemical-light baths.

## THE USE AND ABUSE OF MORPHIN AFTER ABDOMINAL SECTION.

L. H. DUNNING, M.D.

Professor of Diseases of Women, Medical College of Indiana; Chief of Staff of Deaconess Hospital.  
INDIANAPOLIS, IND.

There seems to be a wide divergence of opinion among English and American surgeons as to the benefits of the administration of morphin and other preparations of opium after an abdominal section, if we take the expressions found in medical journals as a guide to the views and customs of operators. The questions we propose to briefly discuss in this paper are: What are the indications for and benefits derived from the use of morphin after abdominal section? What are the harmful influences of this drug when improperly used?

Unquestionably, pain is considered the chief indication for its use after an abdominal section. It is here, however, that the great divergence of opinion regarding the advisability of its administration is manifest. The early operators almost invariably administered a large dose of opium as soon as the patient was placed in bed or had recovered from the effects of the anesthetic.

The form of this drug was usually laudanum and the

method of administration by the rectum. The first dose was followed by others as soon as the patient began to complain of pain. At the present time it seems to be the consensus of opinion among most operators that some form of opium should be given where the pain is very intense. Of late codein has come into general use and is given hypodermically or by suppositories. The advantages of this drug are that it does not constipate and is not liable to be followed by vomiting. It is, however, transient in its effects, so that it must be repeated, and even then it is of little value for relief of pain except in the mildest cases. The writer in his practice has endeavored to substitute codein for morphin, but has found it of little value. The administration of one grain of codein hypodermically will modify the pain and will give comfort and rest for one or two hours, but not longer. So little benefit have I derived from its administration that I have almost abandoned its use for the relief of pain. There are those, and they are not a few, who condemn the use of morphin in toto after abdominal section.

Some two or three years ago the writer listened to a paper read by a prominent operator who condemned the use of morphin in the strongest terms. Some one asked him what he would give to relieve pain if it were severe, and his reply was, "nothing," that he would encourage the patient to bear the pain; in the discussion which followed his paper, he remarked to his interrogator: "If you would avoid the use of opium in any form, your mortality would be reduced 5 per cent." These statements were very positive and yet seemed to meet with the approval of many of the operators who listened to him. The last statement we think, however, was far from the fact, as the recorded experience of some of our most successful operators show. They have attained their very low rate of mortality while using this drug.

I cite but one instance, that of Mr. Tait in his prize essay upon diseases of the ovaries. He states that he had just completed a series of 100 consecutive ovariectomies with but two deaths, and a little further in the same chapter he says: "Should there be pain after the operation, I direct the use of a suppository containing one-fourth grain of morphia; but with this agent I am extremely cautious, for my patients never get a single dose of morphia or opium more than is absolutely necessary to relieve pain. Like other operators, I have long since discarded the routine use of opium, which was the fashion at one time, a practice brought into existence by the idea that it prevented the occurrence of peritonitis." Undoubtedly, Mr. Tait in these statements has given us the key to the rational employment of this most efficient drug.

Dudley,<sup>1</sup> in his recent work, has cogently stated the objections to morphin and opium in the following language: "Opium and its preparations lock up the secretions, induce nausea, arrest peristalsis, cause distension, mask other symptoms which might otherwise give warning of approaching danger; they moreover counteract the influence of cathartics and would therefore prove a serious obstacle if it became necessary to move the bowels. Such drugs, if given at all, should be given with the greatest circumspection."

The writer is in accord with facts and principles stated in this quotation. Let us, however, consider their objections somewhat in detail to see if they may not be counteracted.

The first is it locks up the secretions. Under the old methods of preparatory treatment, when water was withheld and the patient actively purged by salines, the dimi-

1. Dudley: Diseases of Women, p. 137.

nution in the amount of urine, the dryness of the skin and costive condition of the bowels were very noticeable and very distressing. Now, that copious draughts of water are given several days in advance of operation and a large enema of normal salt solution given immediately after the operation, these objections are largely removed.

That many patients suffer of nausea and vomiting as the effect of an injection of morphin, there can be no question. I know of no way of effectually preventing this most unpleasant and often serious after-effect of the drug, but since I adopted the plan of questioning the patient regarding the effects of the drug upon former occasions of its use and avoided giving it to those whom it invariably nauseates, I have had much less annoyance from this source. The administration of morphin combined with atropin soon after section is usually objectionable on account of the excitement of the heart's action and the dryness of the tongue and throat the atropin induces. A second minute dose of morphia as the nausea begins is not infrequently effectual in preventing this symptom.

Morphin does arrest peristalsis, cause distension and counteract to some extent the action of cathartics. However, these objectionable features may be largely counteracted by the administration of a rectal injection of normal salt solution after the operation and by the subsequent rectal injection of milk of asafetida, and by the systemic yet prudent use of the colon tube.

The early action of the bowels is conducive to a quick recovery of the patient. It has long been the practice of the writer to secure an action of the bowels within the first forty-eight hours. This is accomplished sometimes by an S.S. enema, at other times by an enema of four ounces of the saturated solution of Epsom salts, to which has been added one ounce of glycerin or lastly, in case of failure of the above-mentioned measures, by the administration of small doses of calomel followed by a saline.

In cases of extreme restlessness the efficiency of an opiate is most marked. Every abdominal surgeon has seen many marked illustrations of this fact. One recently under my observation was most striking. The patient, a school teacher 43 years of age, was operated upon by vaginal hysterectomy for the extirpation of a fibroid uterus, pus tubes and a small ovarian abscess. The operation was not difficult and was quickly done by the ligature method. The patient was one of those extremely nervous persons who are intolerant of pain or restraint of any kind. She was loud in her complaint of pain and so restless that it was difficult to keep her in bed. Two one-grain doses of codein were given and also one rectal injection of hot water containing 20 grains of sodium bromid and 15 grains of chloral hydrate, all with little or no effect. The administration of one-sixth of a grain of morphin quickly brought relief and quiet, calm sleep. It was not followed by an unpleasant symptom. The whole aspect of the case was changed and the patient went on to a speedy and comfortable recovery.

Persistent vomiting, not due to peritonitis or obstruction of the bowels, but of reflex origin, is not infrequently relieved by the administration of one-eighth grain of morphin.

The place of morphin in the treatment of post-operative peritonitis is far from being settled. My own experience leads me to avoid its administration except in rare cases, such, for instance, as those in which the bowels have acted freely and in which there is no vomiting, yet there is great restlessness and pain. Even in such cases it is so apt to induce vomiting that it should be

prescribed with the greatest circumspection. In sepsis all are agreed that morphin is harmful.

The chief etiological factors of post-operative peritonitis are trauma and infection. Recognizing this the surgeon is prone to become dogmatic and absolutely proscribe the drug. Unquestionably, not a few valuable lives have been sacrificed because the attendant or nurse would not heed his dogmatic statement.

There is another condition concerning which I would speak of the use of morphin, viz., in those individuals who are addicted to the use of the drug. The terrible depression, great restlessness and acute pain caused by withholding morphin from such persons, added to the shock and other dangers of the operation, may be the determining cause in producing a fatal issue. Immediately following an abdominal section is not the time or occasion to break the morphin habit. It is, however, an appropriate time to begin diminishing the accustomed dose, so that a little later it may be entirely withdrawn.

In secondary shock occurring one, two or three days subsequent to the operation and due to fright or over-anxiety and accompanied by great restlessness, the administration of a small dose of morphin is often followed by a calm sleep and entire relief of the patient. I am aware that there are those who deny the presence of secondary shock and who teach that so-called secondary shock is a condition due to secondary hemorrhage. I wish to cite one of my cases illustrating my idea of secondary shock. Mrs. A. was operated upon in a private hospital by abdominal section for the extirpation of a small pyosalpinx. The operation was an easy one, the patient reacting well. Everything went on in a normal manner for thirty-six hours, when a patient who had undergone a severe operation, was placed in a bed across the hall from her. The newly arrived patient suffered intensely and was boisterous, crying out in agony that she was dying. My patient heard her every moan and outcry, became frightened and much agitated. Her temperature fell, her pulse became rapid, her skin blanched and respiration sighing.

This is the condition I found her in half an hour after the serious symptoms appeared. She was moaning and turning in bed and begging piteously for her friends, whom she wished to see before she died. For a little while I halted between two opinions, now thinking it was shock and now secondary hemorrhage. We applied heat and friction to the surface, and gave stimulants hypodermically. In a short time a bright spot appeared upon one cheek and one ear became livid. It was plain to my mind we had to deal with shock. I directed a large high enema of hot water and the administration of one-eighth grain of morphin. I sat down quietly by her bedside and assured her that she would soon be better and would recover. In a few minutes her restlessness gradually disappeared. She became calm, then drowsy and finally slept. The sleep lasted for an hour. During that sleep the surface of the body warmed and the color returned. She awoke at the end of an hour refreshed, and at the end of four or five hours every evidence of shock had disappeared except that she was fatigued. Morphine played an important part in the restoration of this patient. I wish to briefly summarize as follows:

1. The routine use of morphin and other preparations of opium are to be condemned.

2. For the relief of severe pain and marked restlessness morphin is much superior to codein, though more prone to be followed by unpleasant symptoms such as nausea, vomiting, diminished secretions and constipation of the bowels.

3. The serious after-effects of morphin may be largely overcome by the drinking of liberal quantities of water before the operation and the rectal injection of a pint or quart of the normal salt solution immediately after the operation, the systematic use of the colon tube and the early action of the bowels.

4. In persistent vomiting not due to sepsis or peritonitis, small doses of morphin hypodermically not infrequently affords relief.

5. In secondary shock due to fright or overanxiety morphin in small doses is often a potent remedy.

#### SOME POINTS IN THE DIFFERENTIAL DIAGNOSIS OF ABDOMINAL AND PELVIC TUMORS.\*

RUFUS B. HALL, M.D.

CINCINNATI, OHIO.

To men who devote their lives to this special work this is a difficult problem. Even in the hands of such men positive diagnosis is not always possible before the abdomen is opened, and not always then until the tumor has been examined under the microscope. It is only fair to make this statement in the beginning as a reason for not drawing the differentiating lines very acutely. We must bear in mind that there may be exceptions to the usual rule in many of the symptoms in any given case. He who takes written notes and keeps a record of his cases for future reference will be doubly repaid for his time in his future work. No better method of informing oneself in this line of work can be suggested than the careful note-taking of every case that passes under observation.

In studying the differential diagnosis of abdominal and pelvic neoplasms it is essential to keep in mind the normal anatomy of the regions involved. The history of the case, showing where the tumor was first noticed or the pain first felt, will often aid us in our diagnosis as to the nature of the disease. If, from the clinical history, we can learn that the tumor was first observed, when quite small, in the region of the gall-bladder, it would give us a suggestion for a provisional diagnosis. Often the early location of the tumor was the normal location of the healthy organ from which the tumor developed, and a knowledge of its relations is of great clinical importance.

Certain methods of examination are essential and the physician who uses them systematically is not nearly so likely to be misled as one who does not do so. The methods are inspection, palpation, percussion, mensuration, auscultation and exploratory puncture. For examination the patient should be placed upon the back on a smooth, level surface, a high table or a smooth, hard bed. The head should be slightly elevated. The clothing should be removed and the patient protected by a suitable covering.

For inspection the abdomen should be entirely exposed to view. The position of the body, the general appearance of the abdomen, the location of the tumor and its outlines, should be carefully noted.

During palpation as during inspection, the patient should be on the back. The patient's knees should be slightly elevated, resting upon a pillow. The physician should attract the patient's attention by ordinary conversation, about something not pertaining to the disease, if possible. It is important not to cause the patient pain by rough manipulation. The parts should be manipu-

lated carefully and gently, absolutely no force being used, otherwise the object is frustrated. The physician should not overlook the simple precaution of having his hands as warm as the patient's body. This is only a little thing, but it is the aggregation of little things in our profession that makes the difference between success and failure. By palpation we may detect cancer of the pylorus or pancreas, floating kidney, abdominal aneurysm, mesenteric and omental or peritoneal growths, small ovarian and uterine tumors, with almost as much certainty as we make a diagnosis in pneumonia. We must not give an opinion, though, at this time, for we want to be as certain as it is possible for man to be before we risk one. The sensation of the patient as to pain and the degree of spasm of the abdominal muscles will give some definite idea of the local inflammation present and of the character of the tumor. The appearance and manner of the patient will tell us whether the pain is hyperesthesia, hysteria or real pain. Note particularly if one portion of the abdomen is more sensitive than another. Try to determine whether the tumor contains fluid or is solid. After gaining all the facts that are possible in this position, the patient should be turned on the side, with the knees flexed. This may reveal entirely new symptoms that could not be elicited with the patient on the back. For instance, floating kidney can always be palpated in this position when it would entirely elude us with the patient on the back. Then, with the combined vaginal, abdominal and recto-abdominal examination, new facts may be gained. These will give us clues to our diagnosis which we can work out to a reasonable certainty in a few moments afterwards.

For percussion the patient is again placed on the back, with the abdominal muscles relaxed. The whole abdomen and flanks should be carefully gone over and every abnormality and dull region noted and marked out on the patient's skin with a pencil of soft lead. When this has been done the patient should be changed first to one side and then to the other and the whole region gone over again. Abnormal conditions should be carefully noted in the changed positions, especially if the abnormality changes its position. Deep and superficial percussion should be carried out carefully, as much valuable information can be gained thereby. Rest the left hand upon the abdomen, using each finger as a pleximeter. Spread the thumb and fingers, allowing one or two fingers to extend over the edge of the supposed growth and the rest beyond it. Carefully percuss each one in turn without moving the hand, and note the different sounds. This will often give positive knowledge of dulness where the ordinary mode of percussion would not. We can readily determine the borders of the supposed tumor and whether it is solid, fluid or gaseous.

Auscultation is not so valuable an adjunct as the preceding methods, but it has its place. This is especially true in supposed intestinal obstruction. We can trace peristalsis of the intestine which is always present in that condition. In not a few instances it will save the physician the chagrin of pronouncing a normal pregnancy an abdominal neoplasm, or confounding an aneurysm with other forms of tumors.

Many good men recommend exploratory puncture or tapping, but the more I see and do of this work the more I am convinced it is rarely necessary or advisable to tap, and that it is not devoid of danger. Men who operate often do not advise aspiration as a means of differential diagnosis in abdominal and pelvic tumors. The reason is logical and just. If a tumor causes enough

\* Read before the Northwestern Ohio Medical Association, at Lima, Dec. 14, 1901.

trouble to demand relief and a differential diagnosis can not be made, we had better not add the risk of an accident following tapping, but reserve our opinion until operation has been made.

#### DIFFERENTIAL DIAGNOSIS OF OVARIAN CYST.

As an illustration of the methods to be employed we will consider the differential diagnosis of an ovarian cyst of moderate size—say somewhat smaller than an adult head. The clinical history is of great importance. Menstruation is not changed in type in any way. The patient complains of a little pelvic discomfort. The tumor is of but few months' duration or perhaps has but just been discovered. The patient is not ill, but alarmed at the discovery of the lump and seeks advice. First note the appearance of the abdomen, whether or not the tumor is more prominent on one side than on the other. Ovarian tumors of this size are rarely ever central. The measurement from one anterior spine of the ilium to the umbilicus is greater on one side by half an inch to an inch than on the other. This much variation is scarcely perceptible to the eye. Tumors occupying exactly the center of the abdomen are usually uterine. Palpation reveals a round, usually smooth, semi-elastic tumor, almost always fluctuating. If very thin-walled, fluctuation will be very perceptible, but if the fluid is very thick and tenacious, the sense of fluctuation is correspondingly lessened. Percussion reveals dullness over the entire tumor. Changing the position of the patient will not change the area of dullness.

*From Pregnancy.*—Then come the fine points of differential diagnosis between ovarian tumors and the other forms of tumor that develop in the pelvis and abdomen. The first to be excluded is pregnancy. It is a well-known fact that unmarried women who find themselves pregnant will make misleading statements to their physicians and resort to the meanest subterfuges in order to mislead their families. When the physical signs and condition of the tumor in an unmarried woman suggest the possibility of pregnancy, we must be on our guard, regardless of her statements, and carry our examination to the minutest detail in every particular. By vaginal examination I have been able time and again to convince myself immediately that the patient had been purposely misleading me by her statements and that the tumor was a pregnant uterus. I will say in passing that nearly all the mistakes of my professional friends who have referred cases of this kind to me have come about because they have not made a vaginal examination, either because the patient objected or they thought it was not necessary. A man who has practiced obstetrics a few years can not be easily deceived when the woman is pregnant if he makes a vaginal examination. There will be the usual physiologic changes in the vagina and neck of the uterus. The cervix will not be firm and hard as in a non-pregnant uterus. The speculum will reveal the parts engorged with blood. The vaginal mucosa will have the bluish tinge rarely present at other times than pregnancy. The normal-sized uterine body can not be mapped out, as it is always possible to do if the tumor is ovarian. From external appearance of the abdomen the bulging forward low down is not so marked in ovarian cysts as in pregnancy. Auscultation may reveal the fetal heart sound, and by a little manipulation we may be able to get the fetal movement as well as ballottement with rhythmical contraction of the uterus. If so, everything in the heretofore obscure case is perfectly plain.

*From Fibroid.*—Having excluded pregnancy in our differential diagnosis, the fact of a tumor present still

remains. If the tumor is the uterus itself enlarged, it will not be difficult to map it out by bimanual examination. If it is a fibroid, we will have a hard mass that may be smooth or irregular in outline, non-fluctuating, and with a history of a slow growth. As a rule the patient will have been conscious of the presence of the tumor for many months and usually many years. She has had well-marked menstrual derangement preceding her observation of the tumor. This derangement usually consists of prolonged and excessive bleeding accompanied by more or less pain. It is the first thing that attracts the patient's attention. Many patients bleed from ten to fourteen days at each period. Sometimes the fibroid develops in one wall of the uterus and remains interstitial growth. The uterine cavity enlarges. Not a few of these cases bleed excessively at each period for two or three years, then the period gradually assumes its normal condition, the uterine body contracts to its natural size and the tumor increases in size. The patient will remain quite comfortable until the tumor is large enough to cause inconvenience from pressure. With this clinical history the physician may doubt the correctness of his former diagnosis. Examination will then reveal the tumor subperitoneal, the uterine body of almost natural size and attached to one side of the tumor. This is because the tumor in its early history was located nearer the peritoneal covering than to the mucosa. The uterine contraction forced it out of the grasp of the uterine muscle. The gradual contraction of the uterus controlled the bleeding. If located near the mucosa in the early history of the growth, this same contraction of the uterine body forces the tumor into the uterine cavity and thus we have the true uterine polyp. With these conditions present and a definite knowledge of the clinical history, one should have little difficulty in making a diagnosis.

*From Dropsy.*—One of the most difficult conditions to differentiate is the encysted dropsy of tuberculosis. By percussion the same signs are present as in ovarian cysts. Changing the position of the patient does not change the area of dullness any more than in ovarian cyst. By palpation the apparent tumor is not so easily defined in encysted dropsy. In ovarian cyst the upper edge ends abruptly. In encysted dropsy the adherent omentum and bowel prevent our making out a sharp boundary line of demarcation. When the patient is on her back the tumor itself is not quite so prominent. The abdomen rather flattens out as it does in ascites. We must place our chief dependence upon a careful clinical history, in many cases especially for the year or two preceding the time of examination. The general health will usually have been poor, with progressive weakness and emaciation; yet this is not always true. There is always more menstrual derangement in tuberculosis than in ovarian cyst of small size. Usually the flow is either profuse and prolonged or scanty. The general appearance of the patient is that of a sick woman out of all proportion to what we would expect if the tumor were an ovarian cyst. The pulse is always accelerated. The temperature chart will also be an aid, but we must be careful on that account not to confound encysted dropsy with a suppurating cyst. As a rule there will be found other manifestations of tuberculosis.

There should be little or no difficulty in making a correct diagnosis of uncomplicated peritoneal dropsy. The clinical history will give some clew as to organic disease of the kidneys, heart or liver. The edematous feet and limbs will at once attract our attention. With the pa-

tient on her back percussion will reveal the resonant area in front, a dulness in either flank; changing the position to the side, we will have the resonance changed to the uppermost side and the dulness below, on account of the gravitation of the fluid. By bimanual examination the uterus and ovaries will be found perfectly movable and normal.

If we have the complicated condition of the pelvic tumor with abdominal dropsy it may be very difficult to make a correct diagnosis. We frequently have peritoneal dropsy directly due to the irritation of the tumor, especially if the tumor is malignant. In this condition the physician may mistake the distended abdomen for a large ovarian cyst when the real condition is a small pelvic tumor and peritoneal dropsy, with the intestine adherent to the tumor and pelvic floor in such a manner that they can not float up on the fluid. A careful physical examination will correct this mistake.

#### SPECIAL TUMORS.

*Malignant tumors* in the pelvis are, as a rule, not difficult to diagnose. There is more or less emaciation and loss of strength. The tumor grows very rapidly and there is a tendency to include the adjacent organs until finally all the organs in the pelvis are fixed. As the disease advances pain is greatly in excess of that of non-malignant growths.

A *large suppurating ovary* may be mistaken for an inflamed ovarian cyst or a fibroid uterus. As a rule it will not be difficult to make a correct diagnosis if the clinical history is carefully taken. Illness will have extended over a number of years. There will be deranged menstrual function with more or less pelvic pain all the time. The tumor will be more fixed in the pelvis than a fibroid. It is not always possible to get fluctuation in a suppurating ovary the size of a cocoanut, but it is always possible to outline the uterine body, not much enlarged, on one or the other side. The tumor simulates a fibroid inasmuch as the patient bleeds from six to fourteen days at her menstrual period. I have had these cases referred to me many times for fibroid. By vaginal examination the parts are more sensitive and more fixed than is usual in fibroids. In the majority of these cases there is nothing in the temperature chart that would throw any light upon the diagnosis.

*Ruptured tubal pregnancy* with a large accumulation of blood clot, seen several weeks after primary rupture, may be confusing. Here again the clinical history plays a very important part in the diagnosis. The patient has a previous history of endometritis or salpingitis or both. She has suffered with deranged menstrual function for many months or years. She has missed one, two or possibly three periods and believed herself pregnant. Her illness was ushered in by a sudden, sharp attack of pain in the abdomen, followed by well-recognized symptoms of shock lasting from a half hour to three or four hours. If pregnant not more than seven to nine weeks, she is able to leave her bed the following day and continue her usual vocations. In three or four weeks she has another attack of pain and collapse, when renewed hemorrhage takes place. She is again able to leave her bed in a few days and only complains of a sore abdomen. This may be repeated three or four times before the patient comes under the observation of the consultant. The pelvis and lower abdomen is now filled with old blood clot, forming an apparent tumor. In a number of similar cases I have suggested to the medical attendant that the tumor was blood clot from a ruptured tubal pregnancy. He would reply in a somewhat quizzical

tone, "Why, Doctor, that can not be so. If the woman had a ruptured tubal pregnancy she would have bled to death at once." The fact is, ruptured tubal pregnancy rarely causes death from hemorrhage at the time of the first rupture. If it did, we would rarely see these cases on the operating table. The longer the duration of pregnancy before rupture takes place, the greater the danger of the patient dying from hemorrhage at the time of the first rupture.

The above conditions are more likely to be confounded with each other than any of the remaining diseases, yet many of the other conditions require careful consideration.

*Appendicitis.*—I will only speak of appendicitis with a large accumulation of pus. It ought not to be difficult to diagnose this condition from other abdominal and pelvic tumors. Embarrassing mistakes have been made, however, on more than one occasion by prominent men. The clinical history, the condition present, the fixed condition of the mass, contrast so markedly with other abdominal growths that one can hardly realize how it could be confounded with anything else. It is usually confused with a suppurating ovary on the right side or a right kidney with pyonephrosis. In a kidney tumor the colon is always in front. This can be easily demonstrated by inflating the colon with air. A few compressions of the bulb of an ordinary Davidson syringe, pumping in air in place of water, will make it easily apparent. We can then outline the colon by percussion, perfectly. Carefully analyze the urine for blood and pus. There would probably be a history of attacks of nephritic colic. This would be true of hydro- or pyonephrosis. A floating kidney with twists in the ureter would have a history of sudden attacks of pain. In new growths we are not nearly so likely to have the attacks of pain, but there is one symptom of importance, that is, blood in the urine. Not infrequently in malignant disease of the kidney there is nothing abnormal in the urine either microscopically or chemically. The tumor, if it is a kidney, begins to develop too high up for appendicitis. In appendicitis we have the McBurney point, with rigidity of muscles at the commencement of the illness, rise of temperature, marked constipation and abdominal distension. The illness is ushered in with a sharp attack of pain. The tumor, at first barely perceptible, at the end of twelve or fourteen days is the size of a pint cup or larger, extending from the ilium towards the median line. It rarely extends far enough toward the region of the kidney to be mistaken for a kidney. The patient lies upon the back, the leg of the affected side flexed, with more or less inability to extend it without pain. Upon examination we do not find the tumor occupying the pelvis to such a marked degree as in a suppurating ovary. Besides, in the latter disease, we have the history of uterine and pelvic disease preceding the present illness.

*Enlargement of the liver* with distended gall-bladder should not be difficult to diagnose, yet mistakes occur in the hands of very distinguished surgeons. We may and do have distended gall-bladder from obstruction of the cystic or common duct from various causes. Two of the most common are gallstones and malignant disease. To differentiate which is the cause of the distended gall-bladder, and consequently the enlarged liver, is a most difficult problem and one that can not always be solved before operation. If we have obstruction of the common duct, of course we have jaundice with all its ills. If we will recall the fact that we rarely have gallstones forced

into the common duct as the first indication of their presence, it will give us a clue for provisional diagnosis. In malignant disease about the head of the pancreas and involving the common duct, about the first symptom to attract attention is the slow development of jaundice. There has been a general indisposition of the patient for a few weeks preceding. At the first examination we might and probably would find a distended gall-bladder. On the other hand, if we have a history extending over months or years we have presumptive evidence that the disease is not cancer but gallstones. There will have been sudden, short attacks of pain located exactly in the median line under the ensiform cartilage and not over the gall-bladder. These attacks will be associated with indigestion and followed by a distended gall-bladder, with or without jaundice. I have observed for many years that in the early clinical history of gallstones, that is, before there is a distended gall-bladder or jaundice, the patient always refers the seat of pain to the region of the stomach. They are usually treated for neuralgia, gastralgia, indigestion, etc., before the real condition is recognized. If the distended gall-bladder is of long standing, the liver will be more or less enlarged. If a stone has been forced into the common duct there will be marked jaundice. If the case is a neglected one of long standing, we may have the two conditions present, gallstones and cancer. It is a well-known fact that in many of these cases permitted to die unrelieved, autopsy reveals cancer involving the ducts, as the immediate cause of death. The causative relation between the long continued irritation of gallstones and cancer of the gall ducts, I will not discuss. I referred to this at some length in a previous paper many years ago. It was not generally accepted at that time, but it is now the accepted doctrine of the profession.

A *fecal accumulation* in an exceedingly fat abdomen may be confusing for a time only. A little careful investigation will soon settle the diagnosis. These accumulations become very large, frequently nearly if not quite as large as an adult head. Manipulation reveals the fact that you can make indentations with your fingers. In this condition the patient is not always constipated. On the contrary there may be diarrhea. A few doses of salts and high rectal injections of ox-gall will soon solve the problem. These accumulations are usually found in old women of marked sedentary habits and habitual constipation until the present illness. With this clinical history one ought to have little difficulty in forming a correct opinion.

*Phantom tumors* have been a source of annoyance to young practitioners, and not a few old practitioners have made blunders and pronounced phantoms real abdominal tumors. They simulate an ovarian tumor in appearance and clinical history. But we must not take anything for granted in making our diagnosis in abdominal tumors. This condition emphasizes the fact that superficial appearances may lead us to very wrong conclusions. Percussion in a phantom tumor reveals resonance over the entire supposed tumor. This is not true in ovarian tumors. It is rare indeed for ovarian tumors to contain gas. Phantom tumors always contain gas, for it is a gaseous distension of the intestinal canal that makes the apparent tumor.

After using every other means for diagnosis, if not satisfied, give the patient an anesthetic. If the tumor is phantom it will entirely disappear after the patient is thoroughly anesthetized.

In every condition mentioned in this paper we have

seen errors in diagnosis many times, because the physician did not employ every means at his command to aid him.

I would say in closing, one of the best rules to adopt in making a diagnosis is to give an anesthetic in every doubtful case before expressing an opinion. Under anesthesia you have the patient and the tumor just as they are. Relaxation of the muscles gives you a much better idea of the condition present than you could possibly get otherwise. I do not hesitate to give an anesthetic to confirm my diagnosis, and I would urge you to do so whenever you are in doubt. It often dispels all doubt at once, and converts the heretofore obscure and difficult case into one that is perfectly easy and plain.

## THE BACILLUS COLI COMMUNIS IN HUMAN INFECTIONS.

AUGUST JEROME LARTIGAU, M.D.

Tutor in Pathology, College of Physicians and Surgeons, Columbia University.

NEW YORK CITY.

### INTRODUCTION.

The conception of the *bacillus coli communis*\* as a pathogenic factor in disease begins with its earliest history; and the suspicion at first entertained of a possible relationship to certain human infections has been confirmed from many sources. But with the early development of the idea of pathogenic significance the organism was given undue prominence in disease. Whilst its association with a multitude of lesions as different in distribution as they are varied in character is now clearly established, the closer studies of the last few years indicate that its inciting part is certainly one of less independence than many writers are disposed to admit.

Recent investigations which have enlisted more exact and more comprehensive methods of technique reveal in the lesions in which the colon bacillus is so commonly found, other micro-organisms, especially pyogenic cocci, and sometimes bacteria of the anaërobic class† whose primary importance is more clearly established. For the most part, the rôle of the *bacillus coli communis* is a relatively insignificant one as a primary factor in human infections. It is as an invader of territory already *hors de combat* or previously occupied by bacteria that it ordinarily claims our chief attention.

### DISTRIBUTION.

The colon bacillus appears to be almost ubiquitous in distribution. The idea once held that it belonged exclusively to the alimentary canal of man and animals is now discarded. It is one of the most widely distributed micro-organisms in nature, having been found in water, air, the surface and depth of the soil, milk, etc. This wide prevalence of the organism under these conditions is, however, quite subsidiary to its presence in man and animals. It is certainly one of the most frequent of the bacteria encountered in the natural cavities of man and animals.‡ In the putrefaction of cadavers it has been attributed a conspicuous rôle by Malvoz<sup>2</sup>; and Gordon<sup>3</sup> concluded that it has a similar activity in vegetable decomposition.

\* The distinctions which have recently come into importance between the several varieties of the "colon group" are not maintained in this paper; within certain limitations *bacillus coli communis* usually refers to the type form.

† For an account of its distribution in animals, consult the article of Flint, Jour. A. M. A., 1896, vol. xxvi, p. 410. Levin, in *Annales de l'Institut Pasteur*, 1899, p. 558, has also shown its occasional presence in the intestine of the polar bear and seal; for the most part the intestinal discharges of animals in the Arctic regions were, however, found sterile by this observer.

*Distribution in Human Body During Life.*—The investigations of Escherich,<sup>4</sup> since confirmed by the more elaborate studies of Schild,<sup>5</sup> Szego<sup>6</sup> and others have shown that the intestinal contents of infants remain sterile for some time after birth, the period apparently depending upon the time at which the earliest nourishment is given. Under ordinary conditions of life bacteria make their appearance shortly after birth in all parts of the digestive tract. In many animals the bacillus coli communis, or its near allies, seem to be, as in man, the chief obligatory forms. Whether the micro-organisms enter by the mouth or the anus, and if by the former whether through swallowed air, in water taken at the first bath, or with the infant's first nourishment still remains a subject of conjecture. But although the bacterial flora of the intestine is subject to variations according to the kind of food ingested Lembke<sup>7</sup> has shown that the bacillus coli communis on the whole alone remains constant and independent of diet. Just why it persists as the peculiar denizen of the bowel in most animals is as difficult of explanation as is the source of its early appearance in the infant's intestine. The relative numbers of bacillus coli communis in different portions of the alimentary canal have been variously estimated. The observations of Gilbert and Dominici<sup>8</sup> and those of Cushing and Livingood<sup>9</sup> indicate that there is a gradual rise in the number from the duodenum to the ileocecal valve, at which situation the maximum is noted. When the large bowel is reached there is a marked diminution in the number. Since the establishment of its existence in the normal intestine the frequent presence of this micro-organism in the mouth as a saprophyte has been shown by Vignal<sup>10</sup> and Grimbert and Choquet.<sup>11</sup> As would naturally be expected, it has often been found on the skin, particularly in the neighborhood of the anus, in the vagina, anterior urethra, etc., existing as a harmless invader.

It has been urged by Desonbry and Porcher,<sup>12</sup> and by Nocard,<sup>13</sup> but more especially by Adami<sup>14</sup> and Ford<sup>15</sup> that bacteria not alone reach the deeper structures of the intestine under what appear to be normal conditions, but commonly invade the blood of the portal circulation, and liver and kidneys during life. The phenomenon occurs through the intermediation of the leucocytic emigration which occurs with especial prominence during digestion back and forth through the mucosa to the free surface of the alimentary tract. These leucocytes, while in part undergoing a destruction, in part find their way between the epithelial cells, carrying with them foodstuffs and solid particles, among which may be the bacteria present in the cavity of the gut. Many of the bacteria finding their way into the lymphatic channels or the venules of the portal system are for the most part destroyed and digested by the leucocytes. But by the employment of adequate means it can be shown that even in the healthy liver and kidney in a large number of cases a certain number of living bacteria are present almost constantly. It is most probable, further, that in ordinary health a certain number of bacteria which have not been destroyed by the leucocytes or removed by the lymph nodes or endothelium of the portal system, pass as suggested by the studies of Desonbry and Porcher, either through the thoracic duct or through the liver into the systemic blood. Thus it follows from these observations that there most probably exists a condition which the French term "microbisme latent," or as Adami prefers to designate it, "latent infection."

Experiments which I have recently carried on along

similar lines to those outlined by the above-named investigators, but bearing more particularly upon the relation of such bacterial invasions to liver and gall-bladder infections, amply confirm the main facts as outlined in the previous paragraph.

*Distribution in the Human Body After Death.*—The distribution of the bacillus coli communis in the dead body and the condition of its occurrence are of the greatest interest and highest importance in the interpretation of postmortem bacteriology, more especially when the causal significance of this organism is to be established for any lesion. Definite knowledge of its escape into the general circulation and organs after death begins with the studies of Wurtz and Herman<sup>16</sup> and those of Welch<sup>17</sup> published in 1891. The work of these writers received confirmation in the later researches of Beco,<sup>18</sup> and Achard and Phulpin.<sup>19</sup> These observations not only established the frequency with which intestinal bacteria escape into the blood and tissues postmortem, but tend to show that such invasion may take place with or without apparent lesion of the intestinal mucous membrane during the last hours of life. This view has more recently been reaffirmed by Birch-Hirschfeld,<sup>20</sup> who has added observations of his own in support of this belief. Agonal or postmortem invasion is thus a more or less constant phenomenon, most conspicuous in warm weather, and occurring with especial frequency in the liver, and to a less degree in the kidneys, spleen, portal and heart blood, and bile.

#### THE DEVELOPMENT OF VIRULENCE IN THE BODY.

Under the conditions normally prevailing in the intestine the bacillus coli communis is of relatively low virulence, as shown by the experiments of Dryfuss,<sup>21</sup> Macaigne<sup>22</sup> and others; although in this there seems to be some variation in different parts of the intestinal canal. De Klecki<sup>23</sup> from his studies concluded that it may be of greater virulence in the ileum than in the colon, for instance. My own experience certainly shows no difference in virulence in these two situations, which may be regarded as constant or common. However, general experience abundantly demonstrates that the bacillus is on the whole non-pathogenic, as ordinarily found in normal feces.

But alterations from the conditions normally prevailing in the gut soon increase its virulence. Thus, if the colon bacillus be enclosed in a loop of intestine which is experimentally strangulated, it very soon acquires virulence in the lumen, as shown by the illuminating researches of de Klecki.<sup>24</sup> Mere changes in environment, such as passage of the bacillus into the abnormal situations—through the intestinal walls into the cavity of the peritoneum—may be sufficient to exalt its virulence.

Fermi and Salto,<sup>25</sup> from the results of their investigations, conclude that any abnormal condition of the intestinal mucous membrane, such as would be produced by ligature, cold of the abdomen, too much food, etc., almost invariably increases its pathogenic activity, a fact whose significance in the pathogenesis of colon bacillus infections is far-reaching.

All of the writers appear to favor the theory that the virulence of the bacillus is the result of the growth in the living fluids of the body which are supplied with an unusual amount of albuminous matter by the process of inflammation. The seat of the inflammation, which may either be in the intestine or in other viscera, influences to some extent the degree of virulence. The normal intestine provides food in a most favorable form for assimilation by this organism and from which it forms

indol, namely, peptones, the product of the tryptic enzyme. There is also supposed to be a commensal relation between the cells of the intestinal mucosa and the colon bacillus. In this connection the conclusions drawn by Peckham<sup>26</sup> from a very careful study that while the condition and nutrition and development in the intestine seem to be most favorable, the colon bacillus does not become virulent for the reason, she states, "that its first force is spent upon the process of fermentation, and as long as opportunities exist for the exercise of this function the affinities of this organism appear to be strongest in this direction. Moreover, the contents of the intestine remain acid until they reach the neighborhood of the colon, and by that time the tryptic peptones have been formed and absorbed to a great extent. Under such conditions the colon bacillus has relatively little opportunity to assume an excess of proteolytic activity.

"During the process of inflammation in the digestive tract a very different condition may exist. The peptic and tryptic enzymes may be partially suppressed. Fermentation of carbohydrates and proteid foods then begins in the stomach and continues after the mass of food is passed on to the intestine. The colon bacillus can not, therefore, spend its force upon fermentation of sugars, because they are already broken up and an alkaline fermentation of the proteids is in process. It also can not form peptones from the original proteids, for it does not possess this property, and unless trypsin is present it must depend upon the proteolytic activity of other bacteria for a suitable form of proteid food. Perhaps the bacteria form an albuminoid molecule, which, like leucin and tyrosin, can not be broken up into indol, and thus there might be caused an important modification in the metabolism of the colon bacillus which may have either an immediate or remote influence upon its acquisition of disease-producing qualities, for my own experiment indicates that the power to form indol and the actual forming of it are to some extent an indication of the possession of pathogenesis."<sup>27</sup>

It has further been conjectured that pathogenic activity of the colon bacillus for man may depend on changes of environment—the result of growth in a new host of like or unlike species—such as might create alterations in the normal physiological activities of the bacillus, possibly similar to those suggested by Peckham. This view that the disease-inciting properties may depend upon just such changes brought about by transmission through new and unnatural hosts, has more recently been further emphasized by Theobald Smith.<sup>28</sup> I am inclined to lay great stress upon this as a factor in the development of virulence under some conditions.

The direct action of the colon bacillus is, however, due in part at least to irritating chemotactic substances in its protoplasm shown by the work of Pfeiffer, Kalle, Loeffler and Abel, and by the more recent studies of Vaughan and Cooley.<sup>29</sup> The last-named investigators give the following conclusions:

1. The colon bacillus in virulent form contains within the cell a toxin which is fatal to guinea-pigs of from 200 to 300 grams weight, in quantities of less than 1 mg.
2. The aqueous extract of the cells of the colon bacillus grown on agar is inert.
3. The entire germ is resistant to heat, and to dilute acids and alkalies.
4. The cell wall of the colon bacillus is digested by the prolonged action of the gastric juice which does not alter the toxin.
5. The toxin as thus obtained is insoluble, or but

slightly soluble in dilute acid, but is slightly soluble in water and more readily in dilute alkalies.

6. This toxin responds to the ordinary proteid reactions.

7. The toxin, after being freed from the cell membrane, is not destroyed by being boiled.

#### RESUME OF LESIONS IN WHICH THE *BACILLUS COLI COMMUNIS* HAS BEEN FOUND.

*General Considerations.*—The study of the wide anatomical distribution of lesions which may be induced by the bacillus coli communis is of the greatest clinical interest to surgeon and physician alike. Although a great diversity of colon bacillus infections has been described, for most of them, however, the assumed causative significance of the bacillus is unwarranted. If, as the researches of Adami and Ford seem to indicate, this organism may be present in the viscera and blood under normal conditions during life, the difficulties of the problem of the relationship of the colon bacillus to various lesions—especially when the frequency of postmortem bacterial migration is considered—becomes enormously increased. While to the writer few of the reported cases are convincing, still the recital of the cases indicates the class of lesions in which the organism is particularly apt to be found, sometimes being the primary exciting factor, more often, however, having only the interest of a secondary invader.

The caution necessary in the interpretation of autopsy bacteriological findings, particularly with reference to the bacillus coli communis, is admirably shown by the experiences of Veillon and Joyle,<sup>30</sup> and Charrin and Veillon.<sup>31</sup>

From a liver abscess which had on previous examinations been found sterile the first named observers finally obtained the colon bacillus in a subsequent examination; this was clearly a case of secondary invasion. The observation of Charrin and Veillon relates to a case of peritonitis in which pneumococci were present in large numbers during life, but twenty-four hours after death the colon bacillus alone was obtained. Equally interesting are two experiences of my own which further emphasize the limitations of postmortem bacteriology with reference to this organism. In an acute fibrino-purulent pleuritis in the exudate from which the diplococcus lanceolatus had twice been isolated unassociated with other bacteria, a third examination made two hours before death revealed, as did also that made at the autopsy, only the bacillus coli communis. In another case of septicemia with peritonitis from which the streptococcus pyogenes had been cultivated from the blood during life, two agar and blood serum cultures similarly made from blood withdrawn from one of the veins after sterilization of the skin six and two and one-half hours before death contained the colon bacillus alone. In both cases the autopsy findings would have failed to show the real primary inciting factor. As examples of agonal invasion of the blood of the general circulation these cases are most instructive.

*Circulatory System.*—In a considerable number of instances the colon bacillus has been credited with inciting general infection, starting either from local lesions of the intestinal mucous membrane or from the surface of the body,<sup>32</sup> from an angiocolitis,<sup>33</sup> from a cystitis,<sup>34</sup> or from the uterus.<sup>35</sup> Infections with the bacillus coli communis may give rise to any of the multiple and varied manifestations of septicemia including purpura. Gwyn<sup>36</sup> has reported an interesting observation of general infection with a paracolon bacillus, the clinical

symptoms of which suggested typhoid fever. Eisenhardt<sup>37</sup> and Kerr<sup>38</sup> have both reported instances of general infection of puerperal origin. Phlebitis, particularly in puerperal women, has also sometimes been associated with infection with the same organism by Wurtz<sup>39</sup>; and Hartmann and Luffering<sup>40</sup> have reported cases of hemorrhoidal phlebitis in which it was found. Personal experience with bacillus coli communis bacilemia is limited to a single conclusive case, the history of which was as follows:

Mary L., aged 57 years, before onset of present illness had been bedridden for six months owing to an advanced locomotor ataxia. The family history was unimportant; the patient's personal history showed evidences of syphilitic infection twenty years before. Nine weeks before death there gradually developed a large lumbosacral bed-sore which sloughed ten days later. The oval ulcerated area measured 11 by 9 cm.; and until death continued to discharge a considerable amount of thick, yellowish-brown foul-smelling material. An occasional slight evening rise of temperature had been noted since the development of the sore—1 degree. Two days after having accidentally fallen out of bed, but with no apparent damage, the patient suffered from a chill, followed by moderate fever of an extremely irregular type (100.2 to 104.5). The pulse rate remained steadily between 105 and 120. Moderate diarrhea developed on the third day after occurrence of chill; finally on the sixth day low muttering delirium was observed and continued to the end, which occurred on the eleventh day following the chill. On the third day the patient's spleen was just palpable on deep inspiration; and the liver dulness was possibly a trifle increased. The heart was not perceptibly enlarged, but a soft systolic murmur which had not been present before on the fifth day heard all over the cardiac area, loudest at the apex.

The blood was examined on the fourth day, with the following result: Reds, 3,208,940; leucocytes, 19,700; hemoglobin, 55 per cent.

Dried specimens stained with Ehrlich's triacid stain showed moderate poikilocytosis, but no nucleated reds were observed. The differential count (500 whites) resulted thus: Small mononuclears 5.7 per cent.; large mononuclears and transitionals, 3.8 per cent.; polymorphonuclear neutrophiles, 89.6 per cent.; eosinophiles, .9 per cent.

*Urine.*—Uniform cloudiness from the third day on. Previous examinations had shown it to be clear, pale, of low specific gravity and containing hyalin and granular casts with small amounts of albumin. Daily examinations of the urine during this last illness showed practically the same thing; the albumin and casts were, however, increased in amount and after the third day the urine remained persistently cloudy. With this appearance, numerous short, active motile bacilli and some pus cells were observed in the urine; they persisted throughout the disease.

*Bacteriological Examinations During Life.*—Five c.c. of blood were withdrawn on the second and sixth days, respectively, from one of the veins at the bend of the elbow after thorough sterilization with soap and water, ether, 1 to 500 bichlorid mercury (alcoholic solution) and then alcohol. Aërobic agar plate and blood serum tube cultures were prepared from the blood. In all the cultures, particularly in the plates, a moderate growth occurred. This consisted of a single organism whose morphology was similar to that of the predominant organism in the bed-sore pus. It grew well on all media, decolorized by Gram's method, fermented glucose, coagulated milk, produced indol; clouded broth and Dunham's solution; it appeared as a thick yellowish or white growth on potato; and was moderately motile in young cultures. In all other respects it acted like the bacillus coli communis.

On the fourth day similar cultures were made from the urine and pus of the lumbosacral ulcer. From both the bacillus coli communis was also obtained from the urine in pure culture, and from the ulcer associated with small numbers of the staphylococcus pyogenes albus.

*Summary of Autopsy Findings.*—The autopsy was made one

and three-quarter hours after death. The revised anatomical diagnosis, corrected by microscopic study of sections of the removed tissues, is as follows: Degeneration of the posterior cord columns (tabes dorsalis); fresh vegetative endocarditis of mitral valve with chronic interstitial myocarditis; chronic diffuse nephritis; acute splenic tumor; calcareous atheroma of the thoracic and abdominal aorta; slight fatty atheroma of coronary arteries; congestion of the intestine with swelling of the solitary follicles of the ileum and colon.

*Autopsy Bacteriological Findings.*—Cultures were taken from the blood of the right auricle, mitral vegetation, left lung, liver, gall-bladder, spleen, both kidneys, urinary bladder, and marrow of right femur. Agar plates and blood serum tube cultures were made and incubated in air and in a hydrogen atmosphere. The bacillus coli communis was demonstrated in all cultures. No other organisms were found.

The virulence of the bacillus obtained from the heart's blood was tested on two rabbits. The first rabbit (1927 grams) received a one-half cubic centimeter of a 16-hour broth culture intravenously; profuse diarrhea followed and it died 21 hours after the inoculation. The lymphatic apparatus of the intestine was found swollen and the mucous membrane congested. A small amount of cloudy fluid containing leucocytes was also present in the pericardial sac. The second animal (1711 grams) was inoculated with the same amount of the same culture in the peritoneal cavity; it died in 15½ hours. The autopsy showed diffuse purulent peritonitis. The bacillus coli communis was recovered from the blood of the heart in both animals, and from the peritoneal exudate in the one and that of the pericardium in the other.

Endocarditis in colon bacillus infections, such as occurred in this case, has already been pointed out by Gilbert and Lion,<sup>41</sup> Thierloix,<sup>42</sup> Macaigne,<sup>43</sup> and Etienne,<sup>44</sup> and Rendu.<sup>45</sup>

#### ALIMENTARY TRACT AND ACCESSORIES.

No other micro-organism has been given such prominence in the bacteriology of the gastro-intestinal tract as the bacillus coli communis. This is sufficiently explicable by its almost constant presence in the various inflammatory lesions usually in considerable numbers. There is scarcely any portion of the alimentary canal in which it has not been found associated with greater or less inflammatory lesions, sometimes in pure culture, more often concomitant with one or more other bacteria. Thus, even in the angina of scarlet fever it has been attributed an occasional inciting part by Bourges.<sup>46</sup> And Widal,<sup>47</sup> Bouloche,<sup>48</sup> Lermoyez,<sup>49</sup> and Newcomb,<sup>50</sup> have observed its presence in simple acute angina, whilst Blasi and Russo-Travalli<sup>51</sup> have pointed out its frequent association with the diphtheria bacillus in diphtheria. In the less acute forms of sore throat it has also been sometimes given importance by Lermoyez, Helme, and Barbier,<sup>52</sup> and Hudelo and Bourges.<sup>53</sup> The colon bacillus has also been found in a pharyngeal abscess by Wurtz;<sup>54</sup> in this case, however, the streptococcus pyogenes was also present in the exudate.

The following case of colon bacillus angina came under my own observation. The patient was a hospital orderly, 27 years old, whose family and personal history were good. For the two months prior to the illness of interest here, he had been doing hospital work in a ward containing numerous typhoid fever cases. One morning following the usual day's work he was awakened by the pain of a severe sore throat. Examination that morning showed the presence of swollen lymph nodes about the angle of the jaws and a thin grayish membrane covering the left half of the pharynx and irregularly spreading over a good part of the tonsil of that side. The neighbor-

ing mucous membrane was intensely congested. The breath was fetid. During the next twenty-four hours the membrane formation continued until it covered most of the posterior wall of the pharynx and part of the uvula. The right tonsil remained uninvolved. The fever was at no time high; it ranged from 99.6 to 102.4 F. Beyond local pain and some malaise the patient's condition after the second day approached more and more the normal, when on the fourth day he was fully well.

**Bacteriological Examination.**—Smears made from the membrane and stained with Loeffler's methylene blue contained large numbers of short, thick bacilli, which readily decolorized by Gram's method. A few rather large oval cocci sometimes single or arranged in pairs, sometimes as tetrads (*micrococcus tetragenus*) were also observed. Agar plates and blood serum cultures made at the same time contained, beside a few colonies of the *micrococcus tetragenus* and *staphylococcus pyogenes albus*, cultures of an organism morphologically and culturally like the *bacillus coli communis*.

The bacillus had been looked upon as an especially active pathogenic factor in diffuse disease of the intestine because of its increased numbers and exalted virulence whenever inflammatory disease of the parts has existed. Epidemics of infectious enteritis have been referred to a modified and more virulent form of the colon bacillus. Since the early observations of Wyss,<sup>55</sup> and Huetppe<sup>56</sup> upon cholera nostras the investigations of Baginsky,<sup>57</sup> Eserich,<sup>58</sup> Mace and Simon,<sup>59</sup> and others<sup>60</sup> have suggested its importance in the pathogenesis of cholera nostras, cholera infantum, and other forms of enteritis. By the studies of Booker,<sup>61</sup> Cumston,<sup>62</sup> and Nobécourt,<sup>63</sup> it has been shown, however, that in these lesions, organisms, particularly cocci, of known pathogenic activity, are usually coexistent with the colon bacillus. This is of the greatest importance in any analysis of the significance of the *bacillus coli communis* in gastro-intestinal inflammatory lesions. As in many other lesions, its rôle is to be regarded as accessory rather than primary in the pathogenesis of disease of these tissues, an opinion also entertained by Marfan<sup>64</sup> and Fischl.<sup>65</sup>

Similarly, this organism has been regarded by many writers as the inciting microbe factor in dysentery, but more especially by Chantemesse and Widal,<sup>66</sup> Maggiora,<sup>67</sup> Ogata,<sup>68</sup> Laveran,<sup>69</sup> Arnaud,<sup>70</sup> Coutet and Loir.<sup>71</sup> This view has been discredited within recent years.

The rôle of the *bacillus coli communis* in typhoid fever has been variously estimated by different observers. From the fact that it is greatly increased in numbers and virulence in this disease some have felt disposed to attribute to it an important part in the incitement of the intestinal lesions so characteristic of this disease.<sup>72</sup> However that may be, it is wholly secondary to the typhoid bacillus. In traumatic lesions of the intestine the colon bacillus evidently has greater claims as an incitant than in some other forms of intestinal lesions. That it may induce inflammation of the intestine is evident, for it has been shown experimentally and clinically that the virulence of the contained bacilli in strangulated gut is soon exalted, as the experiments of de Klecki demonstrate.<sup>73</sup>

**Peritonitis.**—The literature of peritonitis has been enriched from time to time by valuable contributions made to its bacteriology, mainly by Larnelle,<sup>74</sup> Barbacci,<sup>75</sup> Tavel and Lanz,<sup>76</sup> Grawitz,<sup>77</sup> and quite recently by Flexner.<sup>78</sup> So uniformly has the *bacillus coli communis* been found in pure culture in cases of peritonitis following perforation of the intestine or stomach that it was for a long time accepted almost without question that this

organism is the excitant of the disease in the majority of cases. There has been a radical change of opinion, however, within the last few years, regarding the pyogenic activities of the colon bacillus in peritonitis. The observations of Barbacci suggest that other factors than the colon bacillus must not be disregarded, and that the primary lesions are usually incited by pus-producing cocci. Better methods of bacterial cultivation clearly show that there is in the vast majority of cases concurrent infection. Flexner's<sup>79</sup> experience was a high frequency of the pyogenic cocci in his series, results which agree with my own. However, that the *bacillus coli communis* can not always be considered merely a secondary invader is shown by the reports of Flexner and others.

**Appendicitis.**—Recent studies of the pathogenesis of appendicitis have thrown a flood of new light upon the bacteriological side of this interesting disease. It is now definitely established that most cases of appendicitis begin as a local inflammation of the organ induced by intestinal bacteria. To what extent the different species contribute to the incitement of the process is still unknown. For the most part, I am inclined to believe with Monod,<sup>80</sup> Dieulafoy,<sup>81</sup> Kümel,<sup>82</sup> Achard and Brocha,<sup>83</sup> Darling,<sup>84</sup> and Low,<sup>85</sup> that the pyogenic cocci are ordinarily the primary factors, and the colon bacillus often accessory to the process. Thus Low found the streptococcus pyogenes in 81 per cent. of the cases under three days' duration; in the more chronic cases the colon bacillus was more common. My own experience with twenty-eight acute cases under four days shows the streptococcus in 73 per cent. Adenat,<sup>86</sup> Poncet and Jaboulay,<sup>87</sup> Talamon,<sup>88</sup> Tavel and Lanz,<sup>89</sup> Kirmison,<sup>90</sup> Obrastow,<sup>91</sup> A. O. J. Kelly,<sup>92</sup> on the other hand, assume that the colon bacillus plays by far the predominant rôle in the bacterial origin of appendicitis. A. O. J. Kelly found the colon bacillus in pure culture sixty-nine times in ninety-four cases of acute appendicitis, and the streptococcus present but in a single case. These results do not agree with other recent investigations. A study of cover-slip preparations and the use of more comprehensive methods of cultivation invariably reveal much greater frequency of the streptococcus. Notwithstanding, the experimental observations by Roger and Josue<sup>93</sup> and de Klecki<sup>94</sup> indicate that the *bacillus coli communis* is probably occasionally alone concerned in the incitement of appendiceal inflammation.

Frazier,<sup>95</sup> from the result of his studies on the origin of appendicitis, comes to the conclusion that imperfect drainage from constriction of the lumen or otherwise is the most potent element in the pathogenesis of the process. Such a condition of affairs in his mind leads to an augmentation of the virulence of the contained colon bacillus.

#### LIVER AND BILE PASSAGES.

Under normal conditions the intestinal bacteria are only found a short distance up the common bile duct, but any alteration from the normal, such as mechanical impediment to the outflow of bile, change in the composition of the bile or other perturbation in the physiology of secretion may be followed by an ascending infection of the ducts or gall-bladder with the *bacillus coli communis*, thus inducing angio-cholitis<sup>96</sup> or cholecystitis.<sup>97</sup> These conditions have both been realized experimentally by Charrin and Roger.<sup>98</sup>

A colon bacillus cholecystitis may in turn induce the formation of biliary calculi. Welch<sup>99</sup> was among the first to establish the frequent occurrence of this organism within the interior of gallstones, an observation

since confirmed many times by Gilbert and Dominici.<sup>100</sup> Gilbert and Fournier,<sup>101</sup> Hanot,<sup>102</sup> and Letienne.<sup>103</sup> My own experience showed that the bacillus coli communis was present in about 25 per cent. of the stones examined. This in a general way agrees with the results of observers like Gilbert and Fournier, Hanot, and Letienne. Since the bacterial origin of gallstones was suggested by Galippe<sup>104</sup> in 1886, the importance of this organism in the development of cholelithiasis has been proved by the studies of Mignot,<sup>105</sup> Gilbert and Fournier,<sup>106</sup> and Mieczkowski.<sup>107</sup> My own experiments (to be published later) fully confirm the work of the last-named investigators. All of the studies indicate that the colon bacillus is the most important bacterial factor in the incitement of this lesion.

A variety of lesions of the liver itself have been attributed to infection with the colon bacillus. Thus Achard,<sup>108</sup> and De Vecchi<sup>109</sup> studied its relationship to certain forms of suppurative hepatitis. In infectious icterus it has been found in the blood during life, but of its clinical significance in the disease nothing of a positive nature can yet be said. Lesage and Demelin<sup>110</sup> have more recently ascribed to it considerable prominence in other types of icterus encountered in the newborn. Finally, it has been suggested, more especially by Adami, that this micro-organism is probably of importance in the development of some forms of progressive cirrhosis of the liver. Although this has not been established there are certain points in the experiments of Weaver<sup>111</sup> that tend to lend support to the view that the colon bacillus may induce changes in the liver ultimately leading to cirrhosis of the organ.

#### URO-GENITAL SYSTEM.

All observers are agreed as to the frequent occurrence of the colon bacillus in the urinary tract. When it enters the tissues from the intestine it is frequently excreted through the urine, sometimes thus inducing local inflammatory lesions of the kidney and bladder. Probably such lesions are more often the result of ascending invasion of the tissues, either from the bladder, or from the anterior urethra where this organism has been found as a saprophyte.<sup>112</sup>

In this connection the experiments of Posner and Lewin<sup>113</sup> are of the greatest interest. They found that if the bowel were tied at the anus, and the urethra were ligated, the colon bacillus was found in the bladder. The fluid in the peritoneal cavity between the rectum and bladder remained sterile; but in all instances the kidneys contained the same organism that occurred in the bladder. They concluded that the bacterial exodus took place through the renal tissue and not by direct transmission through the walls and cavities involved. On the other hand, Van Calcar<sup>114</sup> comes to the conclusion from a long and carefully performed series of experiments upon rabbits that in a considerable number of cases of infectious cystitis the infection comes directly from the digestive tract, probably by the subperitoneal path. Both views are probably correct; in women the latter path is evidently common. Th. Brown,<sup>115</sup> from his studies of cystitis, pyelitis and pyelonephritis in women, concludes that the usual mode of infection is by the urethra.

Investigation into the pathogenesis of infectious nephritis has revealed a large class of bacteria which may be considered of importance in the development of the process. Among the micro-organisms the colon bacillus has at different times and by different writers been regarded with varying clinical significance. Partly

from the ease with which it gains entrance into the kidney this organism has been regarded by some observers—Achard and Renault,<sup>116</sup> Fernet and Papillon,<sup>117</sup> Chantemesse and Widal,<sup>118</sup> Jeanselme,<sup>119</sup> Graf<sup>120</sup> and Macaigne<sup>121</sup>—as the excitant of certain descending forms of nephritis. Since the work of Halle and Albarran<sup>122</sup> it has also been regarded as the one most commonly found in ascending pyelitis and pyelonephritis.

It has been assumed that some of the kidney infections were of intestinal origin.<sup>123</sup>

Experience seems to indicate a greater frequency of colon bacillus infection in women than in men. The recent observations of Brown<sup>124</sup> certainly establish the fact that cases of pyelitis and pyelonephritis in women commonly contain this organism in pure culture in the diseased parts, probably due to close proximity of the female urethra to the anus.

Although it is universally conceded that the bacillus coli communis is the micro-organism most commonly found in cystitis the significance of its presence has by no means been definitely established. The French school headed by Guyon has always maintained that it was the most prominent microbic factor in the disease, whilst Melchior, Rovsing, Moullin, and others have contended that other bacteria, mainly pyococci, were of greater importance. This difference of opinion has given rise to a controversy of much interest on more points than one as regards the question at issue. A review of the investigations of Albarran and Halle,<sup>125</sup> Rovsing,<sup>126</sup> Morelle,<sup>127</sup> Krogus,<sup>128</sup> Melchior,<sup>129</sup> Brown,<sup>130</sup> and Douglass,<sup>131</sup> as well as my own experiences, leads to the conclusion that the colon bacillus is, in cystitis, much more often the inciting agent than in any other class of lesions; but that it is the most common primary bacterial factor I am inclined to doubt. It is more probable that it is, as elsewhere, a frequent invader of the bladder, especially when changes have already been induced by other micro-organisms, such as the pyogenic cocci.

In previous studies sufficient attention has not been given to a consideration of concomitant or previous disease, acuteness and chronicity of the cystitis, reaction of the urine, and to the stage of disease in which examination is made, sex and age of patients. Future investigations can not ignore such conditions if more exact knowledge of the bacterial etiology of cystitis is to be attained.

The original infection is, without doubt, very often masked in the long-standing cases by secondary colon bacillus invasion. Then as regards the frequency with reference to sex, the studies of Brown and my own experience show a relatively greater number of cases of acute cystitis among women in which the colon bacillus is present. Thus, among thirty-seven cases of acute cystitis (24 female, 13 male) under ten days, which I studied bacteriologically, 62 per cent. of the women showed colon bacillus as against 35 per cent. for the men. Brown's series of twenty-six cases of cystitis in women following operation contained this organism in 57.7 per cent. of the cases. The mode of entrance into the bladder he believes was ordinarily through the urethra by catheterization, although this procedure was performed with great care. The occurrence of infection under these conditions is sufficiently explicable by the observations of Melchior,<sup>132</sup> Savor,<sup>133</sup> Gorowsky,<sup>134</sup> Bouchard and Charrin,<sup>135</sup> who showed that the normal urethra may contain the bacillus coli communis.

In the reported cases of bacteriuria this bacillus is the micro-organism most frequently encountered; thus

Jeanbran<sup>136</sup> found it fifty-six times in 67 cases, and thirteen times in pure culture. Still more interesting is its relation to pneumaturia as shown by the cases reported by Pere,<sup>137</sup> Favre,<sup>138</sup> Schow,<sup>139</sup> Heyse,<sup>140</sup> and Hall.<sup>141</sup> In the cases of Pere and Hall sugar urine was present, but in the others its absence was specially noted.

Infection, particularly with colon bacillus, has from time to time been suggested by various observers as the important factor in the development of urinary fever; and Achard and Hartmann<sup>142</sup> have published the history of a case in which this was assumed to be the case. Gilbert<sup>143</sup> further believes that "urinary paralysis" may often be attributed to colon bacillus infection; the case which he cites in support of this belief does not carry much conviction.

A variety of other lesions of the uro-genital tract have also been described in which the same organism has been regarded more or less definitely as having clinical significance. Thus Barbacci<sup>144</sup> found it in foci of suppurative inflammation in the prostate gland; and Pezzoli,<sup>145</sup> Pluyn and Laag<sup>146</sup> in the pus of acute urethritis. Malherbe and Monnier<sup>147</sup> have described a case of gangrenous inflammation of the penis, apparently induced by a variety of the colon bacillus. In the cases of epididymitis and orchitis reported by Karo<sup>148</sup> a history of enteritis was elicited; the colon bacillus was repeatedly isolated from these lesions.

This organism has likewise been found in the genital organs of the female in a few cases. Colon bacillus metritis has been described by Gilbert;<sup>149</sup> and Eisenhardt<sup>150</sup> has reported it as inducing puerperal fever. Its presence in salpingitis has been noted; Gilbert and Lion,<sup>151</sup> Raymond,<sup>152</sup> and Gebhard<sup>153</sup> reported instances of this kind. With regard to the last reported case Dr. Welch has pointed out the possibility of its being a bacillus *aërogenes capsulatus* infection. Hall<sup>153 1/2</sup> has very recently described a case of vaginal false membrane in which the colon bacillus was found.

#### RESPIRATORY SYSTEM.

Few cases are on record of the occurrence of the bacillus coli communis as a pathogenic agent in lesions of the respiratory organs. The examples of bronchopneumonia that have been attributed to it have been published by Gilbert and Girode,<sup>154</sup> Levy and Fischer,<sup>155</sup> Mace and Simon,<sup>156</sup> Sevestre and Lesage,<sup>157</sup> Kreibich,<sup>158</sup> Lesage and Mascaigne,<sup>159</sup> Harbitz,<sup>160</sup> and several others. Thiercelin,<sup>161</sup> and Renard<sup>162</sup> have recorded cases of phlegmonous infection supposedly originating in the intestine. Hitzig<sup>163</sup> cultivated the same organism from two cases of what he considers to be primary putrid bronchitis; in both he thought the colon bacillus was the active microbic excitant. Cases of pleuritis sometimes associated with foul-smelling pus have also been reported by Widal and Albarran,<sup>164</sup> Netter,<sup>165</sup> Dumontpallier,<sup>166</sup> Henke,<sup>167</sup> Wendrickx,<sup>168</sup> and Metzel,<sup>169</sup> in which the same bacillus was believed to be the inciting micro-organism.

To this list I am able to add one of acute purulent pleuritis. The case was that of a six-year-old child whose previous history and health were excellent. During the hot weather of August, 1900, the child was taken acutely sick with symptoms of enterocolitis. At the start the temperature did not exceed 101.6 degrees F.; the urine contained a trace of albumin and some hyalin casts on the third day. On the fourth day there was noticed marked dyspnea accompanied by the ordinary symptoms of acute left-sided pleuritis. A leucocyte count made at this time revealed 11,500 leucocytes to

the cm.; for the most part polymorphonuclear (88.4 per cent.). Two days later (sixth day of disease) signs of fluid in the left chest were observed and about 200 c.c. of ill-smelling purulent exudate were removed by the aspirator. The intestinal symptoms continued unchanged for ten days; then gradual improvement occurred. One month after onset of first bowel symptoms the health of the patient was almost fully re-established.

*Bacteriological Examination of Pleural Exudate.*—Five cover-slip preparations of the exudate were stained with Sterling's gentian-violet and searched for bacteria. Numerous short plump rods were observed which decolorized by Gram's method. Cocci were especially looked for but with no success.

Agar plates (aërobic) contained apparently only one organism—a bacillus morphologically similar to that observed in exudate—which in all respects corresponded to the bacillus coli communis. The virulence of the organism was not tested on animals; but it was agglutinated by the serum of the patient as follows: 1 to 10 dilution in 9 minutes; 1 to 30 dilution in 25 minutes.

This may well have been an infection originating in the intestinal canal; as to this, however, proof is wanting. The clinical history alone suggests such an association.

#### NERVOUS SYSTEM.

Practically all of the cases of colon bacillus infection of the nervous system relate to meningeal inflammation, purulent in character. The cases reported by Adenat,<sup>170</sup> Netter,<sup>171</sup> Roux<sup>172</sup> and several others indicate that the character of inflammation does not essentially differ from that which other bacteria may induce. One instance of its presence in a brain abscess has been recorded by Sevestre and Gaston.<sup>173</sup>

I have found the colon bacillus in pure culture in a lumbar puncture fluid. The case was that of a four and a half year old child who had been suffering for eleven days with diarrhea and moderate fever. On the twelfth day symptoms of acute meningitis were observed, and a lumbar puncture made on the following day enabled one to get about 2 c.c. of turbid serum which contained large numbers of polymorphonuclear cells, a few rods, and a small number of short motile bacilli. Cover-slips stained for bacteria showed bacilli morphologically similar to those seen in the hanging-drop specimens; they decolorized by Gram's method. The agar plates and serum tube cultures (aërobic) showed but one organism in every way similar to the bacillus coli communis. The child continued sick with the same symptoms until it died on the fifth day of the meningitis. Cultures from lumbar puncture fluid obtained on the day preceding death gave analogous results to the first. No autopsy was obtained on this child.

#### SENSE ORGANS.

Very few cases of inflammation of the sense organs have been recorded in which the colon bacillus has been regarded of pathogenic significance. Werner,<sup>174</sup> and Jacques<sup>175</sup> found it in suppurative disease of the nose. Both claim that the fetid discharge is characteristic of such infections in this situation. Mercanti,<sup>176</sup> Randolph,<sup>177</sup> and Mazet<sup>178</sup> have described cases of tear duct inflammation in the secretions from which it was also isolated. Bietti<sup>179</sup> reported its presence in a case of blennorrhoea neonatorum. In purulent otitis it has been found several times by Meniere,<sup>180</sup> Guizzetti,<sup>181</sup> Stern,<sup>182</sup> and Baup and Stanculeanu.<sup>183</sup>

#### MISCELLANEOUS FOCAL LESIONS.

Besides the different lesions already mentioned the bacillus coli communis has been found in a great variety

of other conditions in which it has been supposed to be the excitant. For the most part abscesses incited by it have been located in the neighborhood of the digestive tract, more especially the anus. Tavel<sup>185</sup> and Brunner<sup>186</sup> mention cases of wound infection with the bacillus. Suppurative inflammation of the breast,<sup>187</sup> muscle,<sup>188</sup> and bone<sup>189</sup> have been also described. Arthritis is also mentioned as one of the lesions.<sup>190</sup>

Two interesting cases of gaseous phlegmonous abscess have also been described by Dungen<sup>191</sup> and Bunge.<sup>192</sup>

#### CONCLUSIONS.

1. The bacillus coli communis is widely distributed in the normal body and in nature. It is usually present as a saprophyte in all parts of the alimentary canal, and may also be present as such in the lower portion of the common bile duct, on the skin, especially in the neighborhood of the mouth and anus, and in the anterior portion of the urethra and vagina.

2. The bacillus coli communis may, under what seem to be normal conditions, be carried during life from the intestine to healthy viscera. This invasion takes place from the intestine into the abdominal viscera, more especially the liver and kidneys, through the portal circulation. It is possible that similar invasions may take place from other parts, especially the mouth, pharynx, etc. Further, it is probable that under similar conditions to which these invasions occur, bacteria may sometimes reach the systemic circulation.

3. Agonal and postmortem invasion of the tissues of the body is common, occurring with great frequency under the most diverse circumstances with or without apparent lesion of the mucous membrane of the intestine.

4. The virulence of the bacillus coli communis is influenced by at least two factors; 1, changes in the physiologic activities of the intestine; 2, growth in new host environments.

5. The rôle of this organism as a primary inciting factor in infection is infrequent. It is as a secondary invader of tissue previously occupied by micro-organisms, or of tissue already injured from other causes that it claims our chief attention.

6. The bacillus may induce inflammatory lesions, mainly suppurative, in the body tissues generally; the infection may originate in the intestine.

7. Its rôle in acute inflammatory lesions of the intestine, more particularly of the appendix, peritoneum, and urinary passages, has been generally overestimated. Whilst it may be the primary inciting factor, other organisms usually take this part, the bacillus coli communis more commonly acting as an accessory factor.

8. It is a factor of importance in the incitement of cholelithiasis.

## MEDICAL ASPECTS OF CHOLELITHIASIS.\*

ROBERT B. PREBLE, M.D.

Professor of Medicine in the Northwestern University Medical School, Attending Physician to the Cook County Hospital, Mercy, German and Polyclinic Hospitals.

CHICAGO.

It will be quite impossible in the time suitable for an occasion like this to even touch upon many of the important phases of this question and I shall therefore limit myself to those aspects which it would seem desirable to discuss before a surgical society, in other words, to consider the reasons why this disease, which ideally is a surgical one, falls so largely to the lot of the medical man. In the first place, the burden of the diagnosis is on the latter, for the surgeon rarely sees these patients first. Secondly, the medical man is the one who decides which cases shall be operated on and which shall be treated by medical means, for the great bulk of the cases do not require mechanical interference, but any case may at any moment require it and some cases from the outset of the symptoms are inappropriate for medical treatment. We must therefore consider the indications for surgical treatment; and lastly, we must briefly refer to the medical treatment of the cases in which surgical interference is unwise either because of the mildness of the symptoms or because of some concomitant disease or in which mechanical means have failed to give the desired relief.

If gallstones always presented themselves under the typical picture of the gallstone colic, there would be but little difficulty in the diagnosis, but, unfortunately, the pictures are extremely diverse so that often months or even years elapse before the diagnosis becomes clear. Frequently, however, the obscurity of the diagnosis is due to the fact that the multififormity of the symptoms is not sufficiently appreciated and the diagnosis is deferred until a paroxysm of pain is followed by jaundice. Too many are content with making a symptomatic diagnosis such as gastralgia, hepatalgia or neuralgia.

For purposes of diagnosis cases of gallstones may be conveniently divided into two groups, those with colic and those without. For sake of brevity, let us disregard the cases with paroxysmal pain and jaundice as being too manifest to require discussion and consider only the cases of pain without jaundice. Any of the diseases of any of the abdominal organs which ever cause colic may be confused with gallstone colic and some of the diseases of the thoracic viscera and nervous system also are not rare causes for confusion. Some of these errors are easily avoided by careful and systematic examination, others are unavoidable until after the abdomen is open.

Tabes dorsalis sometimes presents a very faithful copy of gallstone colic and I have personally seen several cases of this disease which have been operated on for gallstones. The error is easily avoided provided only the possibility of it is remembered. Attention to the Argyll-Robertson pupil, the Romberg symptom and the knee-jerk will prevent the error. A diagnosis of gallstones in a tabetic should be made only when there is something more significant than paroxysms of pain and tenderness in the region of the gall-bladder. Jaundice following pain with a palpable gall-bladder with or with-

\* Read by invitation before the Chicago Surgical Society, March 5, 1902.

out crepitus, or better still, with the demonstration of a gallstone in the feces, would warrant the diagnosis of gallstones in a tabetic. In a word, the clinical picture of gallstones must be complete and typical to warrant the diagnosis in a tabetic patient.

I have twice seen patients entered under the diagnosis of gallstone colic who had a pleurisy of the right side and nothing else. This error, like the one just mentioned, is easily avoided by an examination which is systematic and not limited to the region of the liver. Why the pain of a pleurisy should be felt over the region of the gall-bladder is not clear, but the phenomenon is probably comparable to the referred pains seen in a wide variety of diseases, for example, the neuralgia of the middle dorsal nerves of the left side so often found with various diseases of the stomach. It must, however, be remembered that the opposite error is also possible, that a right-sided pleurisy may be the result of gallstones. I am reminded of another possibility by a case which I saw two or three years ago with Dr. Herrick. It was a young man who gave a history of a number of febrile attacks which were reasonably interpreted as gallstone colic. Examination showed a localized pleurisy, low down anteriorly on the right side. This was thought to be a pleurisy of the right side, secondary to a localized peritonitis from gallstones, but when the abdomen was opened it was found to be a tubercular peritonitis with pleurisy by extension through the diaphragm and not gallstones.

Lead colic sometimes leads one into an error which may be avoided by attention. The occupation of the patient is usually the key to the puzzle. The lead line along the border of the gums, rarely absent among people exposed to lead intoxication, the localization of the pain in the umbilical region and the freedom from radiating pains, together with the lack of the more characteristic symptoms of gallstones, is usually sufficient to lead to a correct diagnosis. Moreover, the bulk of the cases of lead colic occur in male patients and it always requires a more complete picture to warrant the diagnosis of gallstones in a male than in a female. Greater difficulty will be found with the not uncommon cases of lead poisoning in patients whose occupation does not obviously expose them to lead poisoning. Here attention to the other effects of lead will be of aid, particularly the cardio-vascular, the renal and the neuritic effects.

The differentiation between gallstone colic and the pain of the *ulcus ventriculi* is usually simple, but when found difficult especial attention should be paid to the fact that the gallstone colic comes on generally with extreme suddenness in the midst of good health, while the pain of the ulcer comes on more gradually and is usually obviously influenced by the taking of food. It generally lasts a shorter time than the biliary colic, but the patients are not free from discomfort between the paroxysms as they usually are with the gallstones. Pain radiating to the right shoulder or to the right lower dorsal region speaks for gallstones, especially when followed by chill, fever and sweating. A marked increase in the hydrochloric acid in the gastric juice points to an ulcer, although a similar excess has been seen with cholelithiasis. Youth and anemia speak for the ulcer while age and repeated pregnancies speak for the gallstones.

Far more difficult than the differentiation mentioned is that between gallstones and the indefinite conditions grouped under the purely symptomatic name of gastralgia or neuralgia of the stomach. The subjective symp-

toms of the two conditions may be identical and the physical examination be equally negative in both. The close similarity between the two is clearly proven by the frequency with which the gallstones are diagnosed as gastralgia and less often by the opposite error. The development of a single symptom proving a disturbance of the biliary tract, such as jaundice, even the demonstration of the bile pigments in the urine or a palpable gall-bladder or continuously recurring tenderness in the region of the gall-bladder removes the doubt, but, unfortunately, such symptoms are often looked for in vain. Radiation of pain to the right shoulder, chills with fever, the cause of which is not manifest, particularly in women past the mid-point of life, should suggest gallstones. Attacks of pain in the epigastrium occurring at irregular intervals and often precipitated by psychic influences rather than by the taking of food, particularly in a neurotic patient, suggests a gastralgia. Examination of the gastric contents is often of aid in clearing away the obscurity. One should carry in mind the possibility of this confusion and if a patient, especially a female patient, who is not a neurotic, has several attacks of epigastric pain at frequent intervals even though there may be no jaundice, palpable gall-bladder or demonstration of gallstone in the stools, one should advise an exploratory laparotomy.

It is in such cases as these that the symptoms to which Dienlaffoy applies the name of satellite symptoms are of aid in the differentiation. The gallstone cases are frequently greatly troubled by vertigo, slight or severe, fugacious or persistent, occurring either before or during the paroxysm of pain and even in some cases replacing the pain. Such attacks of vertigo are not infrequently regarded as gastric vertigo, but they rarely occur with the gastralgia. Syncope or rather a distressing tendency to lose consciousness is another sometimes prominent accompanying symptom.

Another of these symptoms is both an aid and a source of confusion. I refer to the chill, fever and sweat which not infrequently accompanies attacks of biliary colic. These are valuable in distinguishing the biliary colic from the renal colic and the gastralgia, with which they are said not to occur, but are a source of confusion because they are with difficulty distinguished from the bilio-septic fever resulting from infection of the bile tracts. Charcot, Penzance, Besnier and others long ago recognized two forms of fever resulting from cholelithiasis, one transient and of relatively slight importance, called by Charcot the *hepatalgic fever*, and the second or bilio-septic fever of serious moment. The explanation of the *hepatalgic fever* is unknown, but it seems probable that it is nothing more than a mild bilio-septic fever. At any rate, I think that we are justified in saying that any patient presenting several attacks of biliary colic with febrile phenomena should be considered as having septic bile tracts and be treated accordingly.

Formerly these febrile paroxysms, simulating as they do the malaria paroxysms, were often diagnosed as malaria, an error the more easily made because there may be accompanying them no more pain in the hepatic region than malaria often causes. To-day we are more liable perhaps to the opposite error, taking a malaria for an angiocholitis. Both errors are easily avoided by careful examination of the blood for the plasmodia and by the therapeutic test of quinin.

There are many other questions of diagnosis which might be discussed, just as those mentioned might be

more fully described. However, the things which appear to me most important have been mentioned about the errors which most easily and most frequently occur.

Having decided that the patient has gallstones, we must decide whether the patient should be treated medically or surgically and often this is much more difficult than the diagnosis. Could we adopt the idea advocated by several in the Surgical Section of the American Medical Association in 1900, namely, that the diagnosis of gallstones is in itself an indication for operation, there would be no need to discuss the question of surgical indications. I am glad to be able to say that the Chicago surgeons, I believe without exception, opposed so radical an idea as this. I know of no clearer demonstration of the absurdity of this position than that given by Professor Kehr. Kehr utilizes the figures of Riedel, who holds that in Germany there are 2,000,000 people with gallstones, of whom 5 per cent., or 100,000, suffer from symptoms; and of these 34,000 are in need of immediate operation. I know of no figures for America, but I am sure that every one of us has seen many cases of gallstones in which an operation could be no more justified than many of the ovariectomies done a few years ago or the hysterectomies done to-day.

Certain of the rules proposed by surgeons do not appeal to me at all. For example, I can see no point to Riedel's rule that one unsuccessful attack of biliary colic is an indication for an operation. By an unsuccessful attack he means one after which no calculus is found in the stools. He infers that the calculus is too big to escape and must therefore be removed, ignoring the fact that one may have an attack of colic without gallstones and that very many stones lie quiet for years even after exciting several attacks of colic. On the other hand, Kehr's suggestion that frequently repeated successful colics are not an indication for operation seems to me to be too conservative.

For a long time I have given my students the following list of indications for surgical interference: 1, frequently repeated attacks of colic; 2, septic symptoms in a patient who has symptoms of gallstones; 3, empyema of the gall-bladder; 4, localized or generalized peritonitis; 5, persistent jaundice; 6, obstruction of the intestines; 7, fistulæ.

Let us briefly consider these. 1. Frequent attacks of colic. This is really a rather indefinite statement for the word frequent is altogether relative. One must consider the character of the patient, the social condition and the responsibilities bearing upon her and a variety of other factors, but to put it briefly we may say that when the happiness or the usefulness of the patient is seriously interfered with by the attacks of colic and when their frequency is not materially lessened by medical treatment, an operation should be performed. It does not seem to me that the success or failure of the attacks has much bearing on the question. Far more important is the bearing of the chills and fever which often enough accompany the attacks. If these symptoms are frequently repeated, operation seems to me to be indicated even though the other signs of sepsis are wanting.

2. Septic symptoms developing in a patient suffering with gallstones. It would be superfluous to describe these symptoms even briefly, for the general symptoms do not differ from those of sepsis wherever its point of origin. In many of these cases operation is futile, but it should be attempted because it is impossible to distinguish before opening the abdomen between the oper-

able and the inoperable cases. If the infection is localized in any one portion of the bile tract or the liver, the chances of success are good, while if there are multiple biliary or peribiliary abscesses, failure is certain.

3. Empyema of the gall-bladder might properly be considered under the second heading but is placed here in conjunction with hydrops of the gall-bladder, both being subsequent to occlusion of the cystic duct. With the empyema the indication for operation is absolute while it is not so clear with the hydrops.

4. The development of either a localized or generalized peritonitis is an indication for operation. It is not necessary to discuss here either the pathogenesis of the peritonitis or its symptoms. A generalized peritonitis is indication for immediate operation, while with the localized inflammation the indication is neither so absolute nor so urgent. The danger of the local process lies rather in its remote than in its immediate effects. The list of possible remote effects of the local peritonitis would be long and such examples as obstinate abdominal pain, pyloric stenosis, obstruction of the intestines are sufficient for illustration.

5. Obstruction of the common duct with resulting jaundice. There can be no question of the absoluteness of this indication. The destructive changes in the liver and the intoxication of the organism as a whole with the bile make relief of the obstruction imperative. The only point for discussion is the length of time we should wait before admitting that the jaundice is permanent. If after eight or ten weeks the obstruction persists, there is little use in waiting longer, although there are numerous instances in which the obstruction was spontaneously relieved even after a much greater period than this. These cases are not desirable subjects for operation because of the hemorrhagic diathesis often resulting from the prolonged jaundice and often requiring a preliminary treatment with gelatin or calcium chlorid to increase the coagulability of the blood.

6. Obstruction of the intestines. It is perhaps inappropriate to include this among the indications for surgical treatment, for in the great majority of cases there have been previous to the onset of the symptoms of ileus, no symptoms of gallstones and the case is not recognized as one of gallstones until the operation shows the cause of the obstruction. Stones large enough to cause intestinal obstruction can not escape through the ductus choledochus and must make their way from the gall-bladder by unnatural passages, by fistulæ between the gall tracts and the intestines. The establishment of such fistulæ is accompanied by no peculiar symptoms. In 92 observations collected by Lobstein, there were but 17 in which the symptoms of the occlusion were preceded by symptoms of gallstones. Of the cases collected by Lobstein, 61 were not operated upon and 31 died; of the 31 operated upon, 19 died. These figures about agree with those of Naunyn, who states that 50 per cent. recover spontaneously. Although these figures indicate a higher mortality in those operated upon than in those not, it is clear to my mind that all cases should receive operation as soon as their nature is recognized. If this is done the mortality falls to a low figure.

7. Fistulæ may be established between the bile tracts and a large number of the organs. Some of these are to be regarded as beneficial, while others, such as the cutaneous fistula, are both an inconvenience and an injury and should be relieved as soon as possible by surgical means.

There has recently been an addition to the list of sur-

gical indications, namely, the development of the fat necrosis. I have no doubt that, now that our attention has been drawn to this effect of gallstones, we will see and recognize antemortem a rapidly increasing number of cases. As the number increases, the clinical picture will become clearer and better characterized. When recognized the indication is imperative.

Mention might also be made of the cancer of the gall-bladder found with gallstones. The question is still open as to which causes the other, assuming that there is a causal relation between them. Should the possibility of cancer resulting from gallstones be an indication for operation? When one compares the great frequency of the stones with the infrequency of the primary cancer of the gall-bladder, there seems no reason for so radical a position. It seems to me more radical than the hysterectomy as a prophylaxis against cancer of the uterus.

Lastly, we must refer briefly to the general plan of treatment of patients who, because of the mildness of their symptoms, the presence of some other disease of more serious moment than the gallstones, or because of the failure of relief after mechanical means have been tried, are to be put on medical treatment. Let me, however, in passing insist upon more careful attention to all the other viscera in cases of this sort than is often given. All too frequently the patient's heart or kidney is irreparably injured in the effort to relieve the gallstones and the patient left in a far worse condition than before and with his life materially shortened. Look out for nephritis, myocarditis, arteriosclerosis, diabetes and lipomatosis.

So far as the medical treatment is concerned, we may dismiss as futile efforts to dissolve stones which are already formed. Calculi are not highly soluble in the test tube and anything we may give by mouth is not likely to dissolve them in the gall-bladder. If any of the various methods which have been tried with this idea in mind have succeeded there is no evidence to that effect. Our efforts must therefore be directed toward preventing the formation of additional stones and the relief of troublesome symptoms. With the first indication in mind we must recall the two essential conditions for the formation of calculi, stagnation of the bile and a lithogenic catarrh of the biliary mucous membrane. We must lessen the stagnation and the inflammation of the mucous membrane. The patients should be urged to give up the sedentary life they are usually leading and take a reasonable amount of outdoor exercise. If they are wearing their clothing too tight or lacing with corset or string, they should be shown the error of their ways. Massage is often a useful adjuvant, although personally I see no use and only possible harm in efforts at massage of the liver and gall-bladder as is advocated by some. A wide variety of diets have been planned and include all sorts of extremes. The best diet is a simple, well proportioned one, taken regularly and rationally and in as small quantity as is compatible with the maintenance of nutrition. Every effort must be made to keep the gastro-intestinal tract in the best possible condition both for the effect this has upon the stagnation of the bile and upon the catarrh of the gall-bladder. In this way the circulation through the mucous membrane is improved, favoring recovery from the existing catarrh, increasing the resistance to new infection and other causes exciting inflammation. The diet and the exercise are probably the most important factors in accomplishing these purposes, but there is also a long list of drugs which have proved themselves useful adjuvants in

cases of this sort. Prominent among these are the various mineral waters and salts. Carlsbad, Epsom, Glauber and others of similar character, mercurials, salicylates and the various gastro-intestinal antiseptics are all used. So far as the treatment of the colic is concerned I think that nothing need be said except to draw attention to the danger of the formation of the morphin habit if the attacks are frequently relieved by this drug. In some cases, indeed, this gallstone morphinism becomes an indication for operation. The truth of the matter, however, is that any patient having attacks of colic so frequently that there is any danger of morphinism, furnish in the attacks sufficient indication for the adoption of mechanical means.

## New Instrument.

### THE PILE SHIELD.

V. PLETH, M.D.  
CHICAGO.

It has often happened, even in the best hands, that the patient has been severely burned, when the ordinary clamp and cantery method has been employed in the operation for piles, causing the surgeon no end of annoyance. To avoid this, I have devised a little instrument that eliminates such acci-

dents: this instrument is small, inexpensive, portable, easily sterilized and does away with the expensive pile clamp and protecting gauze pad. It is an oval-shaped, nickel-plated brass plate,  $2\frac{1}{2}$  by 2 inches, with the edges turned up, except at the lower portion, which has a narrow slit for the purpose of slipping it behind the forceps that grasps the pile mass. In using it the rectum is thoroughly dilated with a rectal speculum,

the protruding pile mass grasped by an artery forceps and an ordinary hysterectomy forceps (Ferguson flat-tipped forceps is admirably adapted) is made to grasp around the base of the pile mass, so that the axis of the forceps is parallel to the axis of the gut. The first forceps is removed and the shield slipped over the pile mass behind the clamp. The cantery in any form is now employed to burn the pile mass away. On account of the elevated rim of the shield, the cantery can not slip over and touch the surrounding skin.

**Salicylic Acid in Strawberries.**—Portes and Desmoulières have succeeded in isolating crystallized salicylic acid from strawberries. The *Gaz. Méd. Belge* of March 13 mentions this curious fact and observes that it is important in the study of adulterating substances in preserves, syrups, etc., containing strawberries.

## ROENTGEN RAYS IN THERAPEUTICS.

Electricity has always been a field for the sanguine therapist and too often a disappointment to the conservative judicious practitioner. High hopes raised by flattering reports of its efficiency have been again and again overthrown by the hard lessons of actual experience and some, like a distinguished German neurologist, have even gone so far as to hold that in the vast majority of cases its good effects have been merely those of psychic impressions, thus practically relegating it to the class of suggestive medicine. Methods of its employment—the Apostoli treatment for myomata for example—have been a temporary craze, to be almost entirely forgotten in a very few years. When d'Arsonval showed some years ago that currents of very high potential might be used on human beings with perfect safety, hope ran high for the eventual discovery of effective electrical treatment. It proved as disappointing as all previous methods of using electricity in medicine. As Prof. Osborn said recently with regard to biologic problems generally, "Life rarely acts according to the reasoning of the closet philosopher. Out of the careful observations of the unexpected, however, is come the *rationale* of the life processes." It may easily be that the pendulum has swung too far in this direction of skepticism, but the effect is the same and the distrust of high claims for new methods of utilizing electricity and allied agencies is the rule with the conservative portion of our profession.

Perhaps it is a good sign that it is now five years after the introduction that the therapeutic effect of the *x*-rays is beginning to be one of the most prominent features in the medical and surgical horizon. There seems some reason for hope from recent reports of conservative observations that this form of radiant energy is not to prove as disappointing therapeutically as have other forms. The morbid effects of the *x*-ray exposures on normal tissues and the precancerous keratosis, observed by Johnston,<sup>1</sup> are suggestive of a similarly hostile action on therapeutic utility. The favorable results reported by Pusey, Allen, Rinehart, Lee and others here and abroad seem to point to a real value of these rays in a large number of cases of malignant disease, and the testimony is increasing. Dr. Pusey's paper in the present issue gives an encouraging, but still a very conservative view of the possibilities of *x*-ray therapeutics. A

like encouraging note has prevailed in quite recent articles by Morton, Hopkins and others, and notably in the discussion of a paper by Dr. F. H. Williams<sup>2</sup> read at the meeting of the New York Academy of Medicine, March 6, 1902.

We are probably just entering on a period when *x*-rays will be extensively used in the treatment of many forms of disease. It is important, then, to realize the limitations and the possibilities of the new therapeutic agent as far as possible. Dr. Coley, at the meeting of the New York Academy of Medicine mentioned, pointed out one of the limitations. In his experience the *x*-rays do not favorably affect rapidly growing malignant tumors at all. Sarcomata, especially those of the round cell variety that so often take on luxuriant neoplastic activity, seem not to be inhibited in the slightest even by long and daily exposures to the *x*-rays. (On the contrary, Pusey reports a rapidly growing round-cell sarcoma which subsided with marked rapidity under *x*-rays.) Other more slowly growing sarcomata are very frequently not only inhibited in growth but induced to take on a shriveling process that leads to their ultimate disappearance. This is true at times, even after a series of operations, when the neoplasm has become absolutely inoperable and death seems inevitable.

In Dr. Williams' experience no external malignant tumor has failed to be benefited by exposure to the *x*-rays. Even in cases where extensive involvement of deep-seated tissues rendered all hope of permanent cure futile and where the progress of internal symptoms showed that the deeply situated process continued to spread, the superficial neoplastic tissues were always favorably affected, the odor of discharges was rendered less intolerable and the discomfort was considerably lessened. The most striking feature of the employment of the *x*-rays by all has been the lessening of the pain associated with the malignant conditions. In cancers *en cuirasse* where the chest was imprisoned as in a vise to the constant intense discomfort of the patient, relief was afforded almost immediately after exposure. In the extremely tender cancers of the breast in which even the weight of clothing becomes insupportable, this exaggerated sensitiveness can be made to disappear. Even the painful conditions associated with cancer of the stomach are assuaged and in some reported cases the patient has been able for a time at least to once more take nourishment.

It would seem, then, that the *x*-rays may be resorted to in all inoperable and painful cancers. Further, in recurrences after operation for cancer, the malignant nodules are often so close to the surface that they form an especially favorable subject for *x*-ray treatment. It is in these cases that the most satisfactory results have been obtained. With regard to superficial epitheliomata the question comes up—shall they be treated by surgical intervention or by the *x*-rays? In any case it is evident

1. Brooklyn Med. Jour., February, 1902.

2. See page 959 in this issue.

at the end of two weeks whether the *x*-rays will be of benefit or not. This is not too long a delay to ask before having recourse to the knife. As in the doubtful cases where there is a suspicion of syphilis the therapeutic test of specific treatment is applied, so in the cases of epitheliomata the possible benefit of *x*-ray treatment should be sought.

Notwithstanding all these remarkable results and the very evident indications from the same, the therapeutics of the *x*-ray is yet in its infancy and a wise conservatism is advisable as regards its future. The promise so far is the brightest, but there is much yet to be learned both as to its possibilities and as to its limitations. With care the exact value of the *x*-rays for malignant disease can be determined without any of the unseemly over-enthusiasm and consequent reactionary disappointment that has characterized the introduction of every new therapeutic agent of any promise during this last quarter of a century. Let us hope that the dignity of the medical profession will not in this matter be compromised before the public as it has been so often under similar circumstances in the past.

#### HUMAN STIRPICULTURE.

The number of articles proposing the prevention of propagation of defectives indicates a widespread interest in problems of improving the human stock. It is apparent that permanent segregation of every individual who may easily be recognized as physically or mentally unfit to be a parent is too great a task for state resources, while permanent seclusion of moral defectives is quite out of the question. The consequence of these conditions is that individuals whose offspring will surely either actively or passively prey on society are allowed to keep on propagating even though they are returned time and again to institutions and secluded. Since temporary segregation is a failure in keeping down the birth-rate of perhaps our worst class of citizens, it is proposed to surgically asexualize by vasectomy or by ligation of the Fallopian tubes those whose progeny are certain to be a menace to society. Already some legislative bodies have taken up the subject and in the future medical men will find themselves called on more and more to express opinion about the value of these measures.

Judgment on the efficacy of this method of ridding the world of degenerates must be formed in the light of many practical considerations. Especially to be remembered is the fact that the biologic forces of degeneracy are always at work even in the best stock. If every existing defective were prevented from producing offspring, yet in the next generation there would be a new crop of degenerates springing up from sources now considered within the pale of mental and physical fitness.

But this problem of the betterment of the human breed has been recently taken up from an entirely different standpoint by Francis Galton, who for a generation

past has been a recognized authority on heredity and inheritance. In the last Huxley lecture,<sup>1</sup> Galton took for his subject "The Possible Improvement of the Human Breed under existing Conditions of Law and Sentiment," calling attention to the nobility of enthusiasm for bettering the human stock. He is very optimistic about the practicability of a movement in this direction, but says that "the possibility of improving the race of a nation depends on the power of increasing the productivity of the best stock. This is far more important than that of repressing the productivity of the worst." Prevention of the birth of children among the worst classes is, to be sure, a commendable object, thinks Galton, but yet the tremendous social and industrial value of an individual of the best class so overbalances the worthlessness of a defective that it is clearly most economical to spend our efforts in getting just these best individuals into the world. Now, the laws of heredity are so well established that surely the most excellent results would obtain from picking out, if such a thing were practicable, young men and women with a view to their ability to produce worthy children. They should then be urged to marry each other at the earliest suitable age and beget a number of children compatible with healthy production and development. As it is at present, many of our best young people refrain from marriage until the childbearing powers are on the wane, because the man is often struggling for a competency and the woman meanwhile is pursuing aims quite unworthy in comparison with the production of fine children.

Galton thinks that medical men might take a large part in determining the fitness of individuals for marriage and in teaching the best that is known about the production and bringing up of offspring. They, in connection with other professional students of the subject, might even give diplomas of especial fitness for marriage so that financial aid might be occasionally offered under properly managed patronage. He acknowledges his plan to be rather Utopian and such, certainly, seem some of the details. The general idea, however, of drawing attention to the racial need of progeny from the best stock can not be commended too strongly. From the days of Lycurgus it has often been pointed out that we do less for the human family in this respect than we do for domesticated animals. Galton does good service in pointing out the rational economy of concentrating efforts for race improvement on the means from which the greatest returns can be expected. There must be radical changes in our social ideals and in our conceptions of the motives for marriage, however, before his suggestions can be put into practice.

#### SHORT CUTS INTO THE MEDICAL PROFESSION.

A rather "practical" contemporary devotes a leading editorial in a recent issue to night medical schools, the same being really an attack on the more modern systems

1. Popular Science Monthly, January, 1902.

of medical education. We have no quarrel with night medical schools provided that they carry out what they usually propose to perform; they meet a certain need and furnish, under decided disadvantages it is true, a medical education to those who are unable to give their whole time to their medical course. Their graduates may be to a certain extent prepared; they can pass state examinations, and make up later for the handicap with which they start. A man who will honestly devote his evenings till late in the night to study, laboratory work and other accessories of a medical course after a day's exertion in some potboiling occupation ought to be one of more than ordinary resistance to fatigue and capacity for work and, if his strength and health hold out, these gifts will tell in his future career. Such a one, however, will always regret that his advantages were so limited, unless indeed he is one of those so-called self-made men who have no appreciation of the true relations of things and are ever lost in self-wonder and love and praise of their makers.

What we object to in the editorial alluded to, however, is not so much its defense of night medical schools, which nevertheless is overdone, as its disparagement of modern medical education; it denounces the latter as superfluous in details, tending to useless memorizing and neglecting the training of the understanding and judgment in practical clinical lines. It says "twenty-five years ago men were turned out of medical colleges sounder thinkers, healthier reasoners and more hard-headed practical men at the bedside than they are to-day from our greatest medical colleges, though they had not memorized as extensively as do the present graduates." If this is true our civilization is getting played out. When one compares the old two-course system of the same lectures over and over again, class after class, that was in vogue twenty-five or thirty years ago, with the laboratory work, graded lectures, and all the other modern requirements of a medical course, to say nothing of the greatly enlarged clinical facilities of a modern medical college, the talk about mere memorizing seems ridiculous enough. It appears, however, to be thought a good enough argument for the "practical man." This, we believe, is an error; those who have striven against disadvantages and won a deserved, not a fictitious, standing in the profession do not glory in their early deficiencies, but regret them.

There has been a great increase of medical knowledge during the past quarter of a century and the student of medicine has to keep up with it. Our present methods of education may not be perfect, but they are an earnest effort to meet the needs of the times. Education has always been, as Mr. Dooley says, something to be fought for and one has to pull it out of its hole by the hair of its head. This was true in the past and still more so in the present, and the honest medical graduate of to-day, if he has had more facilities, has also worked harder and has earned more fully the right to care for the

health of his fellow-men than had those of twenty-five years ago. It is not only right but a duty to discourage short-cuts into the medical profession, and so far as any kind of schools have this aim they deserve only condemnation.

#### THE SIGNIFICANCE OF THE HEMOLYMPH GLANDS.

The blood has always been the object of intense interest to all thinking persons and especially to medical men. Of the various and complicated activities that take place in the lymph glands, the spleen and the bone marrow the most striking and apparently one of the most important is the formation of the various blood corpuscles.

Recently attention has been directed again to certain hitherto rather neglected lymph glands with distinct blood sinuses which seem to occupy intimate relationship to the other blood-forming organs. In this country, Warthin of Ann Arbor has made these hemolymph glands the subject of extensive investigations<sup>1</sup>; and simultaneously investigators in Germany and in Italy have published articles on the same topic. Warthin recognizes two structural types of lymph glands with blood sinuses, namely the splenolymph glands and the marrow-lymph glands, the former being the more numerous and related structurally and functionally to the ordinary lymph glands on one hand and the spleen on the other, while the marrow-lymph glands stand between the common type of lymph gland and the lymphoid marrow of bone. He believes that normally the hemolymph glands are concerned chiefly with the formation of leucocytes and with the destruction of red corpuscles, but under diseased conditions the hemolymph glands undoubtedly take on full blood-forming functions.

These conclusions are based on the study of human hemolymph glands under various conditions. Morandi and Sisto<sup>2</sup> reach contrary conclusions. In the first place they note that hemolymph glands occur (man, dog) quite constantly in the same regions as the ordinary lymphatic glands, from which they are distinguished macroscopically by their smaller size and redder color, and microscopically by containing globuliferous and pigmentiferous cells in blood sinuses. These authors do not appear to recognize the marrow-lymph gland of Warthin as a separate variety. They hold that hemolymph glands are concerned with the destruction of red corpuscles and do not take on hemoblastic activity. When the spleen is removed the number of pigmented cells and cells containing red corpuscles is greatly increased in the hemolymph glands; and when hemolytic substances are given splenectomized animals these appearances become more pronounced, being in fact quite intense. But they did not find nucleated red corpuscles

1. Boston Journ. Med. Sciences, April, 1901 (reviewed editorially in THE JOURNAL A. M. A., May 25, 1901, 1478); Journ. Med. Research, July, 1901; and American Journal of Anatomy, November, 1901.

2. Archivio per le Scienze Mediche, 1901, xxv, 397-434.

or giant cells in the hemolymph glands either under these conditions or when they produced so grave an anemia that blood pigment appeared in the urine. In other words they pointedly announce their belief that the hemolymph glands have no erythroblastic powers.

No doubt this contradiction of results will stimulate to renewed study of the structures in question, and those who know of Warthin's accuracy in morphologic study will feel no hesitancy in expressing the belief that his observations will stand the test of further inquiry.

#### COMMERCIALISM VERSUS SANITATION.

The Paris tradesmen have a new peril to their business welfare and are crying out against the sanitary legislation. It seems that the medical profession is fairly well represented in the French House of Deputies, there being some fifty of our confrères among its members. The result has been that the attention of the chamber has been drawn to certain commercial practices on the part of food purveyors to the public and remedial measures proposed. Moreover, the same influences appear to be acting unfavorably to some of the tariff regulations that work to the profit of the home dealers and the result of all this is the demand at last that medical men and hygienist experts shall be excluded from the legislature. They charge the medical "amateur legislators" with spreading false official reports as to the adulteration of food, intended to ruin the business of the dealers, and assert that any doctor who leaves his practice to become a deputy is *ipso facto* a quack. It is the same old story, commercialism against sanitary reform which is being fought out as it has always been. At present Paris is following San Francisco, but the latter has still a good lead.

#### THE DANGER FROM SURGERY.

The perils of only the most trivial injuries in surgery are well emphasized by the recent death of Dr. Middleton of Davenport, Iowa, referred to in our obituary columns, and the very critical condition of the surgeon who assisted him in the operation. In neither case was the wound which caused the septicemia more than barely noticeable. Even the least abrasion may be fatal with specially virulent infections and one can never be sure that he is not in the presence of such in an operation. In this instance the condition of the operator's system can hardly be credited with much influence as a factor. Both operators became infected and the rapidly fatal progress in one and the threatening condition in the other indicate that it was the special nature of the poison that was alone effective. Surgeons run so many chances without injury that they are liable to forget that in some particular case they may meet with a virus that is overwhelming in its virulence. Even the utmost precautions may not always be a safeguard; it is not known that they were neglected in this case. It is a reminder, such as we have from time to time, that our profession has its special perils from which all our enlarged acquaintance with germs and their toxins can not always save us.

#### THE PHYSICIANS HONORARIUM IN PRESIDENT MCKINLEY'S CASE.

For several months the newspapers have been printing absurd stories regarding the bills sent in by the physicians and surgeons in attendance on the late President McKinley. Some of these stories were so obviously fictitious that no one who had given the matter thought could believe them. We have been told that the total amount of the bills would figure up to \$250,000 and from this down to one-fifth of this figure. Unjust comments on these estimates and unpleasant and caustic criticisms, based on ignorance, have been indulged in and an impression has been created in the public mind that we are to have a repetition of the Garfield experience of large claims and extensive cutting down in the Congressional appropriations. President McKinley, while in the line of his duty, was shot by the assassin Czolgosz, and the expenses of his treatment are therefore properly a public charge and it would have been entirely within the limits of professional ethics and propriety had the attending surgeons presented bills proportionate to the responsibility they incurred. We are authorized to state, however, that as a matter of fact the physicians and surgeons have sent in no bills, have made out no bills, and have fixed no charge in bills for their service. They have declined positively to send in any bills. The question of compensation must be settled entirely apart from any statement made by the physicians and surgeons. We hope this statement will be sufficient to settle all questions in regard to the matter. Whatever amount is paid to the gentlemen who have assumed the responsibility must and will be settled by Congress when and in what manner its judgment may dictate.

#### IATROPHOBIA.

There is a little magazine published by the New England Antivivisection Society called *Our Dumb Animals*. Just why it bears this name is hardly indicated by the contents of its latest (March) number, which is mainly given up to attacks on vaccination. Indeed, other samples of the publication have impressed us with the fact that its management is more interested in fighting the medical profession than in benefiting any class of living beings, dumb or otherwise. What it says does not seriously hurt us; attacking vaccination, for example, is like denying the eternal verities, but we regret to see the spirit and the mental idiosyncrasies that prompt these utterances. Indeed, we can only charitably account for the temper and moral obliquity shown, by assuming a sort of psychic failure on the part of these antivivisectionists. What shall we say of the mental condition of a writer of a recent article in a popular magazine who seems to think that he has unanswerably demonstrated that the same reasons that justify the sacrifice of the lower animals would be valid for that of human infants? The dog, he says, is equal in intellect to the child one year old, is equally susceptible to pain and in point of love and affection much the superior of the two! He asks: "Why not vivisect the child as well as the dog?" The trouble with these antivivisectionists is that they do not seem to be able to appreciate the difference between a man and a dog—they have lost their

human point of view and take, we may say, a general bestial view of things! Following, however, the usual evolution of systematized insanity the persecutory delusions have developed into an aggressive phase; their journalism has become affected with an active iatrophobia—to coin a word for this form of mental aberration—the dumb animals are in the background. The stage of megalomania may next be looked for; like a certain well-known character in fiction, they will set up an image of themselves and call it the divine nature and demand that we shall all bow down and worship. It is a pity and a shame that a morbid and narrow zoöphilily should thus masquerade under the name of humanity and so possess its followers as to lead them to oppose in various ways the best interests and even the temporal salvation of their own kind.

#### SCHOLARS AND THEIR REWARDS.

In his recent article entitled "Some Noteworthy Scholars,"<sup>1</sup> Daniel C. Gilman, formerly president of the Johns Hopkins University, emphasizes that "the merit of a university, in the long run, depends upon the men who are called upon to conduct it." In the course of the organization and development of the university at Baltimore, Mr. Gilman came into familiar relations with many noteworthy scholars who came to the university as guests and delivered open lectures on various subjects. As he recounts in a charming manner some of the peculiarities and traits of the scholars he has known, we meet with the following splendid estimate of the services of scholars: "They and their peers, at home and abroad, are the men by whose learning, investigation and publications, society is carried forward. The world applauds the heroes of great struggles, and it does so rightly; it showers its plaudits upon the great orator; it witnesses, breathless, the achievements of surgeons; it calls our times the age of electricity; and yet it is prone to forget or overlook the hidden workers in the laboratory and the library, the quiet men who are the necessary precursors of those who are devoted to the application of knowledge. It underpays them while they are in service; it rarely thinks of providing pensions for their advancing years, or of giving stipends to their families when premature death interrupts activities; the honors it bestows are the empty privileges of placing after their names a few letters of the alphabet in order to show their academic rank. The world knows little, until they are ended, of the anxieties that harass the scholar when he thinks of his future life—I mean his future life here below; it cares nothing for his family. But these quiet men of the desk and the den, of the pen and the book, of the balance and the lens, are they who have kept alive the traditions of literature and extended the bounds of science." It is interesting to note that Mr. Gilman is very careful to emphasize in this manner the investigative side of medicine and to contrast it with the more spectacular. And the truth of his remarks can not be questioned by any one at all familiar with the situation. The rewards open to real investigators and scholars in the various fields of medicine in this country are indeed so insignificant as yet that undoubtedly many young men of splendid gifts for such work are

forced into purely practical lines. As head of the recent Carnegie Institution in Washington, Mr. Gilman has a good chance to put into actual practice his ideas about pensions for investigators and stipends for their families.

#### FUNCTIONAL ALBUMINURIA.

During the last few years much has been written on the subject of albuminuria without demonstrable disease of the kidneys. Most cases of this sort are properly "cyclic" albuminuria; the albumin is absent upon rising in the morning, appears after breakfast and is usually not present late in the day. It is not influenced by diet, and may even be absent after active exercise. Postural albuminuria is not inaptly applied to this condition. The majority of the cases in persons who are supposed to be in perfect health and in whom no organic disease can be found are discovered accidentally. In many instances life-insurance examinations are instrumental in disclosing the condition. The discussions as to the relation such albuminuria bears to life-expectancy are of little value, as they are based largely upon theories and the conclusions are drawn by men who are apt to give the favor of a doubt to the insurance company. The conditions which underlie the passage of the albumin into the urine are unknown and until these are understood, no rational prognosis is possible. As noted by Mendel and Hooker,<sup>1</sup> in the interesting report of a typical case, all attempts to refer the disappearance of the albumin when the subject is in a horizontal position to attendant circulatory changes in the kidneys is no more than an interesting speculation. If urine contains not only small amounts of albumin, but also renal tube-casts, especially other than a few hyaline ones, the condition is one of nephritis, and not of "cyclic" albuminuria. Because albuminuria is intermittent, it does not follow that it belongs among the variety under discussion. In nephritis the amount of albumin in the urine is also apt to be less in the morning before assuming the upright position, and where there is little albumin it may even be entirely absent at that time of day. The only way to learn what ultimately becomes of these cases is by intelligent observation of single examples through a long period of the life of the subjects and by postmortem examinations of the kidneys. If medical men who accidentally find themselves the subjects of functional albuminuria would make regular and careful observations of their own cases during the continuance of the albumin and publish the results, it would help very much to place us in a position of knowing what is to be expected. Physicians who are so situated as to be able to keep cases under observation for years or during life, would contribute something of value to medicine by studying and reporting them. When the results of such collective investigation is obtained, an intelligent prognosis can be made and a suitable therapy instituted. A sufficient number of cases have been reported to show that functional albuminuria is not infrequent; hence what is most needed is information as to what actually comes of them. It would be wise to watch the condition of the kidneys with more than usual care whenever acute disease or pregnancy occurs.

1. Journal of Experimental Medicine, Oct. 1, 1901, 647.

## Medical News.

### DISTRICT OF COLUMBIA.

**The District's Morbidity and Mortality.**—For the week ended March 27 there were 128 deaths reported, a death-rate of 22.7 per 1000 per annum. Brain disease caused 18 deaths and consumption 17. During the week 7 new cases of diphtheria, 4 of scarlet fever and 3 of typhoid fever were reported.

### GEORGIA.

**Militia Change.**—Dr. Benjamin W. Bizzell, Atlanta, has been appointed captain and assistant surgeon of the Fifth Regiment, G. S. T., vice Dr. Edward C. Davis, resigned.

**Medical Association of Georgia.**—The preliminary program of the fifty-third annual session of the Medical Association of Georgia, to be held in Savannah, April 16, 17 and 18, shows 52 titles.

**Bethesda Medical Staff.**—The staff of the Bethesda Orphanage, Savannah, for the current year is composed of Drs. William E. Fitch, Arthur A. Morrisson, George L. Harman and J. O. Cook, each of whom has a service of three months.

**Graduating Exercises.**—The Medical Department of the University of Georgia, Augusta, held its graduating exercises, April 1. The graduating class numbered 46. The diplomas were presented by Chancellor Walter B. Hill. Dr. Theodore E. Oertel delivered the address to the graduating class and the dean announced the honors and hospital appointments. Atlanta College of Physicians and Surgeons graduated a class of 130, April 4.

### ILLINOIS.

#### Chicago.

**To Russia Again.**—The Secretary of State has appointed Dr. Nicholas Senn a delegate to the seventh international conference of the Red Cross, to be held in Moscow, May 16 to 29. Dr. Senn leaves for Moscow, April 29.

**Undertakers Suspended.**—Health Commissioner Reynolds has suspended the licenses of two undertakers, Bernard McNeil, 2915 State Street, and Jacob Weinstein, 264 West Fourteenth Street, on charges of carelessness and violating the rules laid down for the interment of the bodies of scarlet fever patients.

**The New Broom.**—Since the inauguration of the "oldest-of-the-day" system at Cook County Hospital, the reports of the officers have contained recommendations worthy thoughtful attention. One recommendation is that the number of visitors is too great; a second favors the establishment of a convalescent home, while a third states that rollers should be placed on all beds in the hospital.

**Thousands for Charity.**—The German-American Charity Association has obtained donations amounting to \$12,000, which will be distributed among the following charities: Alexian Brothers' Hospital, German Hospital, St. Elizabeth's Hospital, Chicago Maternity Hospital, Home for Destitute and Crippled Children, Visiting Nurses' Association, Chicago Orphan Asylum, and five non-medical charitable institutions.

**Death-Causes.**—Except from convulsions, pneumonia and scarlet fever, deaths from all the principal causes of death showed a decrease last week. The total deaths reported, 496, indicate a reduction of 8.9 per cent. from the previous week's mortality, but the rate is still 6 per cent. higher than that of last year. The death rate per annum per 1000 was 14.19, as against 13.37 for the corresponding week of 1901. There were but half as many deaths from diphtheria as the week before, and but one death from typhoid fever—the least since June, 1901.

**Rush College Co-Educational.**—The senior and junior years of Rush Medical College will be open to women after July 1. This means co-education in all classes of Rush. Women have been admitted to the first two years since last fall, when the first two classes were moved to the University of Chicago. It is expected that fifty women will take advantage of this change and be found in the upper years of Rush by next fall. Among them will be a delegation from Northwestern Medical College, which has barred women. There are twelve women in the work of the first two years of Rush at the university.

**Post-Prandial Plans.**—A few months ago, after a banquet, it was announced that a large sum of money would be given for the erection of the finest medical college building in the world

and its endowment, the beneficiary being a college which offers to teach "pathies" of all kinds. At a second banquet, held April 2, a similar announcement was made, but the speaker was still not at liberty to mention particulars. Although the property for the site has not yet been bought, the sanguine projectors have already planned that their "Chateau en Espagne" shall be a \$500,000 reality within eighteen months.

**Scarlet Fever Prevalent.**—Scarlet fever has been for some months and still is more prevalent and more fatal in Chicago than at any time in the last seventeen years. Since the first of the year there have been 167 deaths reported from this disease out of a total of 7318 deaths from all causes—a proportion of nearly 2.3 per cent. The nearest approach to this was in 1884, when the scarlet fever mortality formed nearly 2.5 per cent. of the total. Last week there were 243 cases of the contagious diseases reported, of which number 162, or exactly two-thirds, were scarlet fever. During March 644 cases were reported as against 156 in March, 1901.

### INDIANA.

**Hospital Dedicated.**—St. Edward's Hospital, New Albany, was dedicated with appropriate ceremonies, April 8. It is to be under the charge of the Sisters of St. Francis.

**Magnetic Healer Jailed.**—On account of his refusal to furnish bail for his appearance, Charles L. Gilmore, a "magnetic healer," against whom five affidavits have been filed for violation of the state medical law, has been committed to jail.

**Galileo Redivivus.**—Last week an Indianapolis physician, after having been fined \$10 for failure to report cases of small-pox to the local health board, pleaded guilty and then declared that he was still of the opinion that the cases were chicken-pox.

**Fort Wayne Medical Graduates.**—The commencement exercises of the Fort Wayne College of Medicine were held, March 25, when degrees were conferred on a class of nine. After the graduating exercises, the Alumni Association sat down to its annual banquet.

**Dr. Eastman's Illness.**—The condition of Dr. Joseph Eastman still continues to be serious. His health has been failing for several months. During the last two months his condition has changed for the worse. The disease is abdominal and a positive diagnosis has not yet been made. He has been very brave and patient throughout his illness, and in this may lie a hope for his ultimate recovery.

**Doctor Sues Doctor.**—Dr. Francis Kelly, Vincennes, has filed suit for \$1000 for professional services rendered Dr. Welcome B. Sprinkle, Oaktown, in the past two years. In the complaint Dr. Kelly claims that he cured Dr. Sprinkle of an affliction of the foot, thereby enabling him to resume the practice of medicine, and that when he proffered his bill for \$1000 Dr. Sprinkle refused to pay him.

**Indiana Medical Journal.**—At the annual meeting of the stockholders the old board of directors and all the old officers were re-elected. Dr. Alenbert W. Brayton will continue as editor, and Dr. George J. Cook as business manager. The directorate includes Dr. Lewis C. Cline, president; Dr. Hugh M. Lash, secretary; Dr. George J. Cook, treasurer; Dr. William N. Wishard, Dr. Joseph O. Stillson, Dr. Lehman H. Dunning, Dr. John H. Oliver and Dr. Hugo O. Pantzer.

### IOWA.

**University of Iowa Commencement.**—At the thirteenth annual convocation of the State University of Iowa at Iowa City, April 1, forty graduates in medicine were given their diplomas by President George E. McLean. The address of the evening was delivered by President S. B. McCormick, of Coe College.

**Davenport's Deaths and Diseases.**—The annual report of City Physician Charles H. Preston shows a death-rate for 1901 of 15.03 per 1000. There were 530 deaths, of which 60 were caused by tuberculosis, 18 by pneumonia, 10 by nephritis, 25 by cancer, 9 by insulation, 17 by accident, 8 by suicide and 2 by homicide. During the year 1039 cases of infectious diseases were reported, with 31 deaths.

**Regulation of Osteopathy.**—A committee of the House of Representatives has reported to that body a bill which requires that the present state board of medical examiners shall issue certificates to osteopaths who have had at least twenty months' study in an accredited school, and who have passed an examination in all the sciences required for doctors in Iowa. The bill

contemplates that in all respects osteopaths must be qualified to diagnose diseases and be competent to practice medicine. The diplomas of osteopathic colleges will be recognized only for the one branch of osteopathy.

#### MARYLAND.

**The Medical Journal Club** held its annual banquet at the Hall of the Medical and Chirurgical Faculty, April 5, Dr. Henry M. Thomas presiding.

**Dr. Martin B. Billingslea**, retiring president of the Northwest Baltimore Improvement Association, was presented with a handsome silver loving cup by the association, April 1.

**Expectoration Arrests.**—Arrests are being made for spitting in the street cars of Baltimore, and the Health Commissioner declares that he will see the law upon the subject enforced.

**Frederick City Hospital** will be opened about April 15. It has been built at a cost of about \$9000, and contains 3 wards and 16 private rooms, in addition to the operating and service rooms.

**Doctors Elected.**—At a meeting of the Society of Colonial Wars, at Baltimore, April 1, Dr. Bennet B. Browne was elected historian, Dr. Walter B. Platt, surgeon, and Dr. Christopher Johnston, member of the council.

**Graduates and Undergraduates.**—There are 256 students pursuing the regular course for the degree in the Medical School of the Johns Hopkins University and 34 graduate students registered for special courses.

**Personal.**—Dr. Arthur D. Mansfield, Baltimore, will sail for Europe, May 1, to visit English and continental hospitals.—Dr. W. B. Morrison was appointed physician to the Washington County Jail, succeeding Dr. H. S. Herman.

**Correction.**—Referring to the death of Dr. Elizabeth A. Darby, noted in THE JOURNAL of January 18, the dean of the Woman's Medical College, Baltimore, notifies us that Dr. Darby was not a graduate of that institution.

**Deaths and Diseases.**—For the week ending April 5 there were 224 deaths in Baltimore against 177 for the same period last year. Among the causes of death were tuberculosis 31, pneumonia 26, cancer 7, typhoid fever 4, diphtheria 2, smallpox 1. Two new cases of smallpox were reported. There were 43 deaths from cancer in Baltimore in March against 33 for the same month of last year. There was also a decrease of 22½ per cent. in the number of cases of infectious diseases for the same periods.

**Recent Legislation.**—Among bills passed by the late legislature were: 1. To amend State Board of Health law. 2. To amend medical practice act. 3. Omnibus charitable appropriation bill. 4. To regulate sale of poisonous drugs. 5. To provide for the maintenance of the Emergency Hospital at Annapolis by appropriating \$3000. 6. To create a tuberculosis commission. 7. To provide for the appointment of secretary of health board of several counties. 8. To enlarge the powers of the Maryland Medical College. 9. To provide for new buildings at the Maryland Asylum and Training School for Feeble-Minded Children. 10. To authorize the erection of a hospital at Cambridge. 11. To amend the charter of the Presbyterian Eye, Ear and Throat Charity Hospital, Baltimore; and 12. To authorize the appointment of an assistant surgeon-general and a hospital corps in the Maryland National Guard. A bill to forbid vivisection was lost in the legislature, and all sewer legislation for Baltimore failed to pass on account of political jealousies.

#### MINNESOTA.

**Leprosy.**—There are 20 lepers in Minnesota, 6 of whom are isolated and 14 at large.

**Pneumonia Fatal.**—During March, out of the 214 deaths recorded in Minneapolis, 36 were from pneumonia.

**Internes Selected.**—As the result of an examination held, March 26, for the positions as internes in the City Hospital, St. Paul, Drs. A. W. Lewis, St. Paul; Adolph G. Liedoff, Minneapolis; E. A. Meyerding, St. Paul; W. M. Brown, Minneapolis, and Fred D. Rogers, St. Anthony Park, were selected, and Dr. Hugh C. Arey was appointed bacteriologist and pathologist.

**Vaccination Creed.**—About 150 physicians of Minneapolis have signed a statement endorsing vaccination as a preventive of smallpox. Their belief is as follows:

1. That true vaccination is an absolute preventive of smallpox.
2. That true vaccination, with pure lymph, followed by cleanliness and proper care of the vaccinated surface, never did and never will produce a serious sore

3. That true vaccination leaves a characteristic scar that follows on no other cause.

4. That no serious effects ever follow true vaccination and that on the contrary thousands of human lives are annually saved by it.

#### MISSISSIPPI.

**Appropriation for Asylum.**—The legislature has passed the bill appropriating \$127,900 to the East Mississippi Insane Hospital for two years.

**Asylum Burned.**—The Institute for the Deaf and Dumb at Jackson was burned, March 18. The inmates were removed without casualty. The loss is \$40,000.

**Columbus Board of Health.**—The Board of Health of Columbus has been organized with Dr. Arthur C. Halbert as president and Dr. W. G. Brewer as secretary.

**Osteopath Convicted.**—An osteopath, who has been practicing in Biloxi for three months, was convicted, April 1, of practicing medicine without a license, and was fined \$20 and costs. This conviction was due to the concerted action of the local profession. In Mississippi the law passed in 1896 defines the practice of medicine with absolute clearness.

#### MISSOURI.

**Addition to Nevada Asylum.**—An addition to cost \$28,000 is to be erected at State Lunatic Asylum No. 3, Nevada, which will accommodate 150 patients.

**License Revoked.**—The State Board of Health, at a meeting held in Kansas City, April 2, revoked the license of Dr. Henry C. McFall, Mexico, charged with malpractice.

**New Graduates.**—University Medical College, Kansas City, held its commencement exercises, March 26. Dr. James E. Logan, president of the college, was in the chair and Rev. E. D. Morgan delivered the doctorate address. Diplomas were conferred on a class of 29.—Woman's Medical College, Kansas City, graduated a class of 6, March 24. The degrees were conferred by Dr. Nannie P. Lewis and the diplomas presented by Dr. Blencowe E. Fryer.—Kansas City Medical College conferred degrees on a class of 18, March 26. The doctorate address was delivered by Prof. F. H. Hodder, of Kansas University; the degrees were conferred by Dr. John H. Van Eman, president of the college, and the prizes were presented by Dr. Andrew L. Fulton, dean of the faculty.

#### NEW YORK.

**Batavia Hospital.**—The new Batavia Hospital, which has been erected by the women of Batavia, was opened to the public last week. The building cost about \$10,000 and is free from debt.

**Dr. James T. Burdick**, surgeon of the Soldiers' Home at Bath, has resigned and Dr. Warren L. Babcock, St. Lawrence Hospital, Ogdensburg, succeeds him as acting surgeon. Dr. Frank H. Starr, of Bath, is appointed temporary assistant surgeon, vice Dr. Arthur P. Shellman.

**Gifts to Hospital.**—Kingston City Hospital has received a donation of \$5000 from the Hon. Ira Davenport in memory of his mother. The income is to be used for the maintenance of a bed.—Frederick S. Flower, New York, made an Easter gift to Watertown hospital of \$5000 to endow a free bed in the hospital to be known as the Mary Elizabeth Flower bed.

**Medical Law Amended.**—The medical law of the state has been so amended that the Regents of the University of the State may, in their discretion, admit conditionally to the medical examinations in the preliminary subjects—anatomy, physiology and hygiene, and chemistry—applicants 19 years old, who meet the other requirements. Under this amendment the regents have power to grant an allowance of one of the four years of study in a medical school to graduates of college courses, registered by them as entitled to this privilege.

#### New York City.

**Public Expectorators Fined.**—Recently 50 persons charged with violating the ordinance against expectorating in public places were brought into court, and 32 were fined \$5 each.

**Patient Bites Physician.**—The physician of the Hotel Navarre, Dr. J. W. Gibbs, was bitten by a patient suffering from uremic convulsions, and although he immediately sucked the wound, and shortly afterward canterized it, the finger and arm became swollen and decidedly septic.

**Personal.**—Dr. C. H. Catherwood, who has been engaged in studying and practicing among persons sick with pulmonary tuberculosis, has contracted the dread disease himself, and has gone with his wife to Colorado.—Dr. J. H. Girdner has been appointed by Governor Odell a trustee of the State Hospital for

**Incipient Tuberculosis.**—Dr. M. D. Lederman has been made adjunct professor in laryngology and rhinology at the New York Polyclinic.

**Dr. Blinn Held to the Grand Jury.**—Some years ago Dr. Francis Gray Blinn was charged with being concerned in the death of a young woman, but managed to escape the clutches of the law. He has also been in trouble because of accusations that he was practicing medicine under various aliases. In spite of these little unpleasantnesses he has apparently been able to do a thriving business, until a few days ago, when a young woman from Connecticut was inconsiderate enough to die in his "sanitarium." This new streak of ill luck bids fair to be the worst one yet, for there were some very strange doings when the parents of the dead girl came to his office, and sufficient evidence has been obtained from his nurse and others to lead the coroner's jury to hold Dr. Blinn for the action of the grand jury.

#### Buffalo.

**The Emergency Hospital** has been designated by the Board of Aldermen to receive city patients.

**Personal.**—Dr. Herman Mynter, wife and daughter sail in June for a four months' visit to Denmark, Germany and France. —The Board of Supervisors has appointed Herman W. Johnson as medical student to have charge of the hospital at the jail.

**Anti-Spitting Ordinance.**—An ordinance was passed in April, 1902, known as the anti-spitting ordinance. It prohibits spitting upon the floor, seat or any part of a street car or public conveyance of any kind or upon the floor of a passenger elevator or in public places. Violation is punishable by a fine not less than \$2 or more than \$100.

**Doctor Bitten by Rabid Dog.**—Dr. Irving Phillips Lyon and wife have gone to the Pasteur Institute, New York, for treatment of a bite of a supposedly rabid dog. The dog was a pet dog owned by Dr. Lyon, which had been bitten by a wandering dog, and a few days ago developed symptoms of rabies, after having bitten both Dr. and Mrs. Lyon. The dog was carefully observed by the Health Department for further symptoms of the disease, and has developed dumb rabies.

#### OHIO.

**Personal.**—Dr. Arthur F. Shepherd, Toledo, has assumed charge of the Dayton Hospital for the Insane.

**To Exempt Students.**—A bill introduced by Senator Thompson exempts from the state medical examination students matriculated prior to January 1, 1902, and graduating before 1906.

**Columbus Health Department Changes.**—The Director of Public Safety, C. C. Philbrick, removed from office Dr. Herbert M. Platter, smallpox physician. Thereupon Dr. William D. Deuschle, superintendent of health and charities, tendered his resignation, to take effect at once. Dr. McKendree Smith has been appointed poor inspector, secretary of the department of health and captain of the sanitary police.

**Cincinnati Internships.**—Drs. H. Bowles, Muncie, Ind., and Charles F. Souther, Ky., both from the Ohio Medical College, were chosen internes, and Dr. R. C. Kendig, Ashville, Ohio, the alternate for Christ's Hospital. —Dr. R. Wilkinson, a graduate of Miami Medical College, and Dr. Joseph J. Black, of the Ohio College, have been selected internes for the Jewish Hospital. —Drs. Harry Schroer and Edward Davis, both of Cincinnati, have been appointed internes to the German Deaconess Hospital.

#### PENNSYLVANIA.

**Lose Suit Against Doctor.**—The jury in the case of Joseph Defrehn vs. Dr. Francis W. Boyer, Pottsville, to recover damages of \$30,000 on account of alleged unskilful treatment, brought in a verdict for the defendant.

**Dr. Kershner Reinstated.**—The President has signed the bill restoring Dr. Edward Kershner, formerly of Mercersburg, to the retired list of the navy, with rank of medical inspector, and that his name will be sent to the senate immediately.

#### Philadelphia.

**Long in Practice.**—Dr. Michael O'Hara, a graduate of the University of Pennsylvania in 1852, is still in active practice.

**Dr. Carnett Injured.**—Dr. J. Burton Carnett was injured in a collision in St. Louis, recently, sustaining a fracture of the arm.

**Bequests.**—By the will of Mrs. A. P. Biddle a bequest of \$1000, upon the decease of her friend, Mary J. French, is made

to each of the following institutions: The Pennsylvania Institution for the Blind, Pennsylvania Training School for Feeble-Minded Children and the Germantown Hospital.

**New Honors for Dr. Keen.**—A cablegram states that Dr. W. W. Keen has been elected an honorary member of the 31st Congress of the German Chirurgical Association recently in session at Berlin. Dr. Keen has also been elected honorary president of the First Egyptian Congress of Medicine, which will convene Dec. 19 to 23, 1902.

**The Medical Club of Philadelphia**, on April 5, gave a reception to Dr. John A. Wyeth, of New York. Addresses were made by Dr. Wyeth, Dr. Todd of Atlanta, and Drs. Beattes, Rodman and Fulton, of Philadelphia. The subjects discussed were "Reciprocity Among State Boards of Examiners," and "Better Preliminary Preparation for Medical Education."

**St. Joseph's Hospital.**—The report of St. Joseph's Hospital for 1901 shows that 2414 patients were treated in the wards. About 6000 new patients received free service at the dispensaries; upwards of 22,000 visits were made, and 2384 emergency cases were cared for. The tradition of the hospital has been departed from in changing the board of management to a non-sectarian body. The hospital has been completely renovated, including the fitting of wards and corridors with metal ceilings and wainscoting. An x-ray laboratory is being fitted up. A substantial and commodious ambulance house and dormitory for male employes has recently been completed. Dr. E. E. Montgomery is president of the medical staff of the hospital.

#### GENERAL.

**Hawaii Physicians to Speak English.**—It is announced that hereafter no physician unable to speak English will be licensed to practice in the Territory of Hawaii.

**Cholera in Manila.**—The total number of cholera cases, up to April 9, was 184, and 140 deaths. It has been confined to the natives and the Chinese, who, in their panic, conceal the dead in the fields or desert the sick in the houses. The Americans and Europeans have no fear of the pestilence.

#### Smallpox.

**Connecticut:** The annual report of the State Board of Health makes some timely remarks upon smallpox and vaccination. It says: "Connecticut is to be highly congratulated that with a population of over 908,000 there have been only 48 cases of smallpox; at a time, too, when it is prevailing so extensively in other states with which we have such constant intercourse. No stronger evidence can be offered, no more forcible argument can be made, no more convincing proof can exist, than is found in the fact that in Connecticut, as elsewhere, smallpox occurs only in unvaccinated subjects, or in those upon whom vaccination has been neglected for many years. Other methods of securing immunity from smallpox are temporary, untrustworthy, vexatious, expensive, and greatly inferior in every way to the security assured by vaccination." The state board strongly recommends the vaccination of school children as provided by statute. It advises that it be required in large factories where many operatives are gathered daily within closed walls.

**Illinois:** The board of health of Monmouth decided, April 6, that Edward Kimball, a guest of the Hammond Hotel, who had been sick several days, had a well-developed case of smallpox. In consequence 27 occupants of the hotel were quarantined.

**Iowa:** The report for 1901 of the Davenport Board of Health remarks that the attenuated smallpox infection, which for more than two years past has been everywhere prevailing, remains almost non-fatal in Davenport and generally in the west, though taking the country over the deaths so far this year are five times and the reported cases two and one-half times what they were in the same period of 1901. From March 1, 1901, to March 1, 1902, Davenport had 107 cases, though it was free from the disease from August 1 to December 5. The record of the 143 cases since June, 1899, shows not one successfully vaccinated before exposure, within 16 years, and only seven with any trace of a vaccinal cicatrix whatever. Surely no better proof of its protective agency could be required.

**Minnesota:** The report of smallpox issued by the State Health Board for the week ended March 31, gives 231 new cases, reported from 64 localities in 34 counties. No deaths are reported.

**Tennessee:** Dr. James A. Albright, secretary of the State Board of Health, in his semi-annual report makes the following observations regarding smallpox and vaccination: "Since my last semi-annual report on October 1, 1901, smallpox from that date until Feb. 19, 1902, has appeared in 56 counties of the state. During this period there was reported a total of 2060

cases, with a total of 33 deaths, or a death rate of  $1\frac{1}{2}$  per cent. During the same period last year Tennessee had about double this number of cases, as the figures will show—4197 cases, with 98 deaths, or a death rate of about  $2\frac{1}{4}$  per cent.; also during this same period—from October, 1899, to April, 1900—Tennessee had 2591 cases, with 45 deaths, or a death rate of  $1\frac{1}{2}$  per cent. Our reports show that there were present in the state on February 19 of this year only 302 cases of smallpox. Since that time reports from various local boards show the disease to have developed at several additional points over the state; also that the disease has been stamped out altogether at twelve or more points included in our report. At the present time there are not over 250 cases of smallpox in Tennessee. . . . Tennessee has a smaller number of cases of smallpox within its borders to-day than any state of the Union where the disease prevails to any appreciable extent. There has never been a time during the past three years when every local board of health in the state did not promptly respond and do all within its power to eradicate the disease when ordered so to do by the State Board. The local boards have at all times and under all circumstances done everything required, as far as they were able to do, considering the many difficulties encountered, a few of which I have already mentioned, but which I desire to emphasize by reiteration, as follows: 1. The mildness of the disease. 2. Local opposition on account of difference of opinion as to diagnosis. 3. The absence of sufficient authority of law for the enforcement of vaccination. 4. Prejudice against vaccination. 5. In the counties of Middle Tennessee and West Tennessee, where the disease has been exceptionally mild, with a small death rate, or none at all, I have noted a reckless desire among a class of improvident negroes to contract the disease, that they might become pensioners upon the county's bounty and charity. . . . Vaccination, then, according to the experience and observation of Tennessee's health officers, not only protects and renders immune when properly and successfully performed prior to exposure, but even after exposure, vaccination, when performed, serves to modify and reduce to the minimum the virulence of the disease, and, I may add, to such an extent that only one death has afterward resulted, and which might be attributable in part to old age."

Utah: A serious outbreak of smallpox is reported at Vernal.

United States: The total number of cases in the United States on March, 1902, according to the report of the Marine-Hospital authorities, was 24,157, with 707 deaths, which is slightly under 3 per cent. mortality. In the corresponding period of 1901 there were 11,496 cases, with 149 deaths, or above  $1\frac{1}{4}$  per cent.

#### The Army Medical School Graduation.

The fifth session of the Army Medical School, which began Nov. 4, 1901, ended April 4, 1902, with the commencement or graduating exercises. The lecture hall of the National Museum, Washington, D. C., was filled by an interested audience largely composed of the fair sex, among whom the student officers had made many friends during the session. On the platform were Col. W. H. Forwood, the president of the faculty, who acted as master of the ceremonies, the members of the faculty, the Secretary of War, the Lieutenant-General commanding the Army and the Surgeon-General.

Colonel Forwood described the course of instruction through which the class had passed and in conclusion stated that the highest marks were received by Asst.-Surgeon James M. Phalen, to whom would be awarded the Hoff Memorial Medal. Asst.-Surgeons Conrad E. Koerber, Roderick P. O'Connor and Robert U. Patterson made more than 90 per cent., which entitled them to the distinction of honor graduates. A large proportion of the others made high percentages, and none fell below the 70 per cent. required for a diploma of proficiency. These others were Jerome S. Chalfee, Charles C. Geer, Ernest L. Ruffner, George P. Heard, Roger Brooke, Jr., Arthur M. Line, Verge E. Sweazey, Matthew A. DeLaney, Paul S. Halloran, Kent Nelson, Robert Smart, Lloyd LeR. Krebs, William P. Woodall, Charles A. Ragan, William R. Eastman, George William Jean, James F. Hall, Raymond F. Metcalfe and Perry Lee Boyer.

Secretary Root presented the diploma of the School to each of the members of the class in the order of their rank in the Army, after which the Surgeon-General delivered the formal address of the occasion. He spoke of the importance of preventive medicine in military practice. He said the most important function of the Army Medical School is to make the student officers practically familiar with all that is known upon this subject and to prepare them to give expert advice upon all matters relating to the prevention of disease among our soldiers under the various conditions of service. This

had become doubly important since we have come into possession of the Philippines, as our soldiers there are exposed to various infectious diseases which are of rare occurrence, or practically unknown within the limits of the United States.

Reference was made to the suppression of yellow fever in Havana, Cuba, to the methods of protection from malaria and other specific diseases. When he looked back forty-one years to the time when he was a newly appointed assistant-surgeon in the Army and realized how many things of which the medical profession was then ignorant are now known and taught in the Army Medical School, he regretted that he was not now a member of the graduating class, equipped like them for a life of valuable work. Facilities are now afforded at every military post of any importance for bacteriologic and chemical work, and it is expected of the members of this class that they will avail themselves of these facilities not only for purposes of diagnosis in the interests of their patients and of prophylaxis in the interest of the command with which they are serving, but also in the interest of scientific medicine and their fellow man.

Among the enquiries before them are: What are the essential factors in the etiology of beri-beri, of sprue, and of tropical ulcers? What are the principal harmful intestinal parasites in these new possessions of ours? Why is it that malarial fevers prevail in the more elevated regions rather than in the vicinity of the paddy fields of valleys near the sea level? What is the principal habitat of the Amoeba dysenteriae outside of its human host? etc.

The Surgeon-General then referred to the importance of a knowledge of military hygiene on the part of military officers and to the prompt suppression of such a disease as typhoid fever which would follow a full appreciation by them of the method of propagation of this disease in camps, giving as an instance in point the rapid fall of prevalence and deaths in the camps of the Spanish-American war, when the subject became understood and the knowledge acted upon. He concluded: "Finally, young gentlemen, do not forget to apply practically the knowledge of hygiene which you have acquired for the preservation of your own health. Aside from any personal interest you may have in the matter, it is your duty to do so; for, if you contract a preventable disease through your own neglect of the proper measures of prophylaxis, or are prematurely retired from service for Bright's disease, cirrhosis of the liver or some other chronic ailment caused by excesses of any kind, you deprive the government of the services of a valuable trained officer. But enough of advice. You are liberally educated physicians of mature age, and I do not doubt that you will go out after your brief period of special training in the Army Medical School fully equipped for the duties which await you and fully cognizant of your obligations to yourselves, to the profession, to the Medical Corps of the Army and to your country. With best wishes for the fullest measure of success and happiness in the prosecution of your life work, I wish you godspeed."

The Hoff memorial medal was then presented by Lieut.-Col. John Van R. Hoff to Lieutenant Phalen, after which General Miles stepped to the front of the platform and was greeted with applause, which for some minutes prevented him from speaking. "It is a great pleasure to me," he said, "to welcome this graduating class to the service of the United States. You have completed your course and have passed your last test. You are now officers in the Army and well-educated surgeons, and I congratulate you upon the success you have achieved. You have reached your goal by honest, consistent and earnest efforts, and are now ready to begin a career which will bring honor to yourselves and which will consist of valuable service to your country. I congratulate you and wish you all success. I would recommend one thing to you particularly, and that is that your life as an officer and a surgeon be based upon the splendid address which has been delivered to you by the Surgeon-General of the Army. If you study it and always live up to its teachings and doctrines you can not go wrong. In closing, I would ask you always to remember something which should be honored and revered above everything else in your lives. You are now officers. You wear the uniform of the Army, a uniform which will make you honored and respected wherever you go, either in this country or abroad. You should, and I know you do, feel proud to wear that uniform. Yet there is something of which you should be more proud and which you should always endeavor to honor and respect. It is your citizenship in this great free country, the greatest republic the nations have ever known."

The ceremonies closed with the playing of "My Country, 'Tis of Thee," the audience and officers standing.

## CANADA.

**License to Practice in Country Only.**—A bill has been introduced into the legislature in British Columbia requiring the council of medical examiners to admit to practice, without examination, all physicians presenting diplomas from any college of medicine in Great Britain or any of the dependencies. This is subject to the proviso that no such physician shall not be permitted to practice in any municipality without complying with the further conditions of the existing act. The press naturally wants to know why a man who can set a leg in a town of 100 people can not set a leg in a metropolis, and why the country population is not entitled to as efficient medical attention as that of the city.

**Dr. Roddick's bill** has been reported on favorably by the special committee appointed by the House of Commons, and it will come up for its final reading in the near future. Dr. J. A. Kennedy, writing from Nkandhla, Zululand, under date of February 20, complains of the great injustice which is done graduates in medicine of Canadian universities in South Africa. This practitioner was refused registration in the New Colonies, Transvaal, upon the grounds that only graduates who were registrable in Great Britain might register. When Dominion registration is accomplished, as it will be, if Dr. Roddick's bill passes, there will be a means of offering English doctors a recognition of their registration, and thus the disabilities under which Canadians suffer in South Africa and other parts of the empire will be removed.

**Representative in London for McGill.**—An article recently appeared in the *London Times* regarding the excellence of the equipment of the Faculty of Applied Science at McGill University, and the wish was expressed that English students would patronize this institution in preference to the Massachusetts School of Technology. Following this the authorities of McGill have announced that McGill has arranged to hold an entrance examination in London commencing on June 6 next. The intimation is also made that Mr. J. Stuart Horner, a well-known English scientist, has been appointed the honorary representative of McGill in Great Britain. As McGill has recently established a six-year course in applied science and medicine, it may be that we will see some English students crossing the Atlantic yet to take a course of medicine in this country.

## FOREIGN.

**Plague in Brazil.**—Five cases of bubonic plague were reported at Rio Janeiro on March 30, and four deaths at Pernambuco.

**Von Ziemssen's Library.**—The 25,000 works which comprise the late Professor von Ziemssen's medical library, have been purchased by the book store of Gustav Fock, at Leipsic.

**Prof. A. Jarisch** died at Graz from typhoid fever, March 21. He had recently published an important compendium of skin diseases. Jarisch introduced pyrogallie acid into the materia medica.

**Cremation of Plague Victims.**—A petition has been presented to the German Reichstag, signed by physicians all over the empire, asking that arrangements be made for the cremation of the bodies of persons who die from the plague or cholera.

**Berlin Professor in Trouble.**—Professor Schweninger, the private physician of the late Prince Bismarck, and professor in the University of Berlin, has incurred the hostility of the entire staff of the Hospital of Gross Lichterfelde, of which he is chief physician.

**Marey Institute at Paris.**—The French *Chambre des Députés* has appropriated 25,000 francs for the construction of an institute for researches in physiology by the method of graphic tracings, etc. The chief aim is to establish standards for the instruments used, the necessity for which has been proclaimed at various congresses of physiology. Marey's jubilee anniversary was recently celebrated at Paris with much ceremony.

**Sentences for Charlatans in Germany.**—An illiterate charlatan named Rogge has been condemned to a year's imprisonment on account of injury from some of his procedures at Braunschweig. The Chemnitz courts have nearly doubled this sentence for the quack Wolf for a similar cause. He has had a large practice, and this is his seventy-seventh sentence. A faith-healer at Darmstadt has been sentenced to three years' imprisonment for fraudulent practices. The trial of the healer, Schumacher, resulted in a verdict of four years' imprisonment and a fine of 4500 marks.

**Increase of Physicians in Germany.**—Consul-General Oliver J. D. Hughes makes the following report to the Assistant Secretary of State at Washington concerning the prospects of the German medical students:

The *Ärztliche Central-Anzeiger* publishes an article according to which the prospects for the average German physician are by no means hopeful, if not gloomy. The article says that in 1880 at an average one physician was counted for every 3400 inhabitants, in 1900 there was one for every 2000, and in all probability in 1906 the proportion will be one to 1850. At present the total number of physicians in German amounts to 28,500, only 6 per cent. of whom are in the employment of the state. The remaining 94 per cent. get no pension, are not freed from municipal taxes, and most of them are compelled to pay a big house rent. Up to 1906, about 500 physicians will die every year, while 1350 young physicians will come from the universities, so that their number will be increased by 850 yearly. In future doctors will have to study for at least 6½ years; the average student, however, will want a longer time, and spend more than 12,000 marks (\$2850) on his studies, rarely less. It is pretty certain that more than one-half of the German physicians make less than 3000 marks (\$714) a year; an income which compares very poorly with the time and money spent on the medical career. Since about 1885, up to the present time, judges and philologists in Germany reached an average of between 30 and 40 years of age before they were permanently employed by the state, the natural consequence was that a good many of those who could not support themselves, up to that age, either from their parents' or their own private means, turned to the study of medicine. While from 1887 to 1896 the increase of the population amounted to 115 per cent., the number of physicians augmented during that time by 63.8 per cent.

## LONDON LETTER.

## Prevention of Consumption.

At the third general meeting of the National Association for the Prevention of Tuberculosis, the Earl of Derby, presiding, said that the Association had reached a stage when it was content to progress quietly. Though great efforts might be made—such as that of the congress last year—on the whole the work should be to entrench the ground occupied. Last year's congress marked an epoch in the history of tuberculosis and home progress has been steady and satisfactory. In Liverpool the boards of guardians have united and erected two sanatoria for pauper consumptives. At Bradford the guardians have decided to erect one. At Marylebone, Sheffield, Wolverhampton and other infirmaries for the poor endeavors are being made, by adapting existing buildings or by additions to them, to provide facilities for open-air treatment. In the west of England the counties of Gloucester, Somerset and Wilts have taken joint action to erect a sanatorium for the working classes—a matter in which this country is far behind Germany.

## Widal's Reaction in Other Diseases Than Typhoid Fever.

At the Clinical Society an important discussion took place on this subject, initiated by a paper by Dr. Hale White and Mr. W. C. C. Pakes on a case of malignant endocarditis giving Widal's reaction. The case was typically one of malignant endocarditis, the patient dying from cerebral embolism. The blood on June 10 failed to agglutinate typhoid bacilli even in a strength of 1 in 2 and 1 in 20, but not with a strength of 1 in 200. Pure cultures of streptococcus longus were obtained from the blood. On June 29, cultures from the urine collected with every precaution showed the presence of a streptococcus identical with that previously obtained from the blood and a bacillus belonging to the paracolon group. Every attempt which was made to isolate the typhoid bacillus failed. The agglutination test was tried with five different strains of bacilli and with four a complete agglutination was obtained with a dilution of 1 in 20 and with one partial agglutination was obtained with a dilution of 1 in 200. On Sept. 13 the patient died. Blood taken from the heart and the spleen showed the streptococcus longus in pure culture, but no typhoid bacilli could be discovered. The patient never had spots or other signs of typhoid fever, nor were signs of healed ulcers found postmortem. In this case the blood of a patient suffering from malignant streptococcal endocarditis contained certain substances which had the power of agglutinating the typhoid bacillus. Dr. Hale White and Mr. Pakes pointed out the clinical importance of this result in considering the diagnosis between typhoid fever and malignant endocarditis and also alluded to the fact that many observers had failed to obtain a Widal reaction in malignant endocarditis. In this particular case the presence of the reaction could not be due to the patient having had typhoid fever previously, for no reaction was obtained on admission. She was treated with various strains of anti-streptococcal serum, but without good result. Dr. F. T. Foogood referred to the case of a man who inoculated his thumb with septic matter on February 10. This was followed by glandular enlargement and constitutional symptoms with a temperature of 104 F. On March 4 there was epistaxis

and the blood gave Vidal's reaction, but next day the right shoulder-joint and the tissues around were edematous and other joints became involved. On March 10, the blood again gave Vidal's reaction, with dilutions 1 in 10, 1 in 25 and 1 in 50. The patient recovered, but he had presented the clinical features of septicemia, although the blood gave Vidal's reaction.—Dr. J. W. Carr remarked that the paper raised the question of the value of Vidal's reaction. He referred to the case of a child aged 5 with symptoms and physical signs typical of acute tuberculosis mainly affecting the lungs, yet the blood tested at the Jenner Institute gave a marked Vidal's reaction.—Dr. C. R. Box said that it was most important to indicate what dilutions were used. At first with low dilution he had gotten reactions with diseases other than enteric fever, 1 in 50 was the most suitable dilution for obtaining the true test in cases of actual enteric fever. Turning to the question of nomenclature, he thought that it would be much better to call this test the agglutinative or serum reaction.—Dr. W. Lee Dickinson referred to a case of gastric ulcer which was erroneously diagnosed during life as enteric fever on the strength of the agglutinative reaction with typhoid cultures.—Dr. Poynton remarked that his experience at St. Mary's Hospital led him to the conclusion that although the test was not infallible it was a most valuable guide. A great deal must depend upon the technique and the dilution of the culture and on the particular strain used, and this to some extent diminished the value of recorded cases.

#### Success of Women as Surgeons.

At the annual meeting of the recently established new Hospital for Women, of which the staff are all women, Sir Thomas Smith, surgeon to St. Bartholomew's Hospital, said that the surgical work done had shown the capacity of women for successfully performing all the operations which were performed on their sex. Upwards of 1900 obstetrical cases had been attended without a single death connected with the process of parturition, though the normal fatality was 1 in 500; 577 major operations were performed with a mortality under 6 per cent. He had attended the operations in the theater and had nothing but admiration for the great celerity and dexterity which he had witnessed.

### Book Notice.

**OPHTHALMIC MYOLOGY.** A Systematic Treatise on the Ocular Muscles. By G. C. Savage, M.D., Professor of Ophthalmology in the Medical Department of Vanderbilt University. 8vo. Cloth. Pp. 589. Illustrated by 61 Cuts and 6 Plates. Price, \$4.00. Nashville, Tenn.: Published by the Author, 139 N. Spruce Street.

It is somewhat remarkable that, in view of the numerous and extensive publications that have from time to time appeared from the pens of American writers on the ocular muscles, their physiology, their pathology and the treatment of the various anomalies of muscular balance, so little or so comparatively little space has been devoted to the physics of the subject. Whether one accepts the conclusions or not, the chief attraction of the book before us lies in the attempt to lay down certain fundamental principles based upon experimentation in the dynamics of the eye muscles—particularly of the extrinsic muscles. Having accepted these theories the mysteries of heterophoria are, according to the author, readily explicable.

We are, ourselves, mainly interested in the challenge given to the Helmholtz law of direction and to the reality of Listing's plane. As is well known, the latter is an imaginary vertical plane, which, passing through the centers of the eyes, always contain their axes of rotation in whatever direction they are turned. Savage, on the other hand, claims that the axis of rotation always lies well within the *equatorial* plane of the eye and not necessarily within the plane of Listing. A very material alteration in the well-known law of Listing is called for if the author be correct. In any event, he supplies this demand on page 54, and furnishes us with a restatement that certainly seems plausible, and which, we do not think, will be readily controverted: "When the line of fixation passes from its primary to any other position, the angle of torsion of the eye in this second position is the same as if the eye had arrived at this second position by turning first about the vertical axis and then about the horizontal axis." This would mean, of course, that the eye in its second position would

have its vertical axis still vertical and its horizontal axis still horizontal.

Again, as is well known, Helmholtz taught that the lines of direction of all objects in the visual field intersect at the nodal point just posterior to the crystalline. Savage suggests that this is an incorrect or misleading statement, and that it would be nearer the truth to claim the intersecting point for the center of retinal curvature, which, he adds, is also the center of rotation of the eye.

Our author, while agreeing in the main with the contention of Maddox on the subject of ocular torsion, believes that undue rotation of either eye on its visual axis is prevented by the oblique muscles, and that, practically, the vertical axes remain parallel to each other and the meridian plane of the head. He very properly rejects the ideas that formerly prevailed and that are, even now, held by some observers as to the simplicity of the oculo-muscular movements. We especially recommend a perusal of Chapter I, particularly of the section "The Individual Muscle and Its Plane." As the author's views are introductory to the work itself, the following quotation will be germane to this review: "The extrinsic muscles do not act alone. In every act of binocular single vision the triple task imposed on the twelve muscles by the imperious law of corresponding points, must be performed. The keeping of the visual axes in the same plane is the chief work of the superior and inferior recti, but they are aided in this work by the obliques, which are also sub-vertors and 'super-vertors.' The intersecting of the visual axes at the point of fixation is the chief, sometimes the only, work of the interni and externi; but the interni are helped by the superior and inferior recti, so that the point of intersection may not be beyond the object; while the obliques assist the externi to prevent the intersection from taking place between the observer and the object. The paralleling of the vertical axes of the eyes with the median plane of the head is the chief work of the obliques, but in doing this work they are hindered rather than helped by the recti. In subversion the superior obliques aid the inferior recti, but at the same time the former must counteract the mischievous outward torsioning effect of the latter. In superverting the eyes the inferior obliques help the superior recti, but the former must oppose the inward torsioning effect of the latter."

The chapter on Cyclophoria should be perused by every student of ocular myology, not only because of the inherent practical importance of the subject, but because it is handled by the man with whom the whole matter is original (although he generously credits his associate, Price, with the name) and who has certainly presented it in a clear and concise manner.

The management of cases of muscular imbalance and the rules laid down for the treatment of every possible form of heterophoria and heterotropia also constitute a most valid claim upon our gratitude. Whether or not we suspect that the enthusiasm of the writer occasionally lead him to expect operative and other remedial results denied to the ordinary ophthalmologist, yet definite and even dogmatic assertions at least command attention and challenge investigation. Space does not allow of reference to even the most important of the subjects comprised in the twelve chapters (whose perusal we commend to every ophthalmologist) but we do not think that much fault will be found with them by even the most conservative or carping critic. If a minor criticism were to be made we would like to join issue with Dr. Savage in the advice he gives (page 566) as to one of the ways of dealing with astigmatism—"give at once a full correction . . . as shown by the ophthalmometer." Not only do we believe this advice to be unwise in that it almost always adds many woes to the unfortunate so treated, but because we agree with Donders that the astigmatism of the cornea is usually greater than the total astigmatism of the refracting surfaces of the eye, and, of course, an ophthalmometric correction is commonly an over-correction. Another minor point is the binding of the book. We believe that a volume of nearly 600 octavo pages, filled with matter as good as this, deserves a stronger and better covering—an affair that, happily, can be adjusted in the second edition.

## Married.

- H. P. Moulton, M.D., Petersburg, Ill., March 18.
- C. Bret Pool, M.D., to Mrs. Alice B. Barnes, both of Lowell, Mass., March 19.
- Frank Walker, M.D., Wichita, Kan., to Mrs. Irene Owen of Topeka, Kan., March 20.
- Henry Barton Jacobs, M.D., to Mrs. Robert Garrett, both of Baltimore, Md., April 2.
- C. M. Denny, M.D., to Miss Myrtle Bradshaw, both of New Brighton, Pa., March 26.
- James Ditmar Voorhees, M.D., to Miss Louise Brown, both of New York City, April 2.
- Graham Street, M.D., to Miss Margaret Colt Bryan, both of South McAlester, I. T., March 25.
- H. C. Nickolai, M.D., Milwaukee, Wis., to Miss Mary E. Tremain of Saginaw, Mich., March 29.
- Livingston L. Lewis, M.D., Hoboken, N. J., to Mrs. Gus Itkins, of North Bergen, N. J., March 20.
- Edward R. Henning, M.D., West Liberty, Ohio, to Mrs. Lulu Mae Hamer of Bellefontaine, Ohio, March 26.
- Arthur Gray Sage, M.D., Buffalo, N. Y., to Mrs. Elizabeth Smith Alexander of Dunkirk, at Buffalo, March 26.
- Benjamin W. Cornwell, M.D., Buffalo, N. Y., to Miss Lydia M. Bates of Batavia, N. Y., in Grace Church chantry, New York City, March 11.
- Thomas Miller Morrow, M.D., Altoona, Pa., to Miss Laura Virginia Greene, superintendent of the Cottage State Hospital, Philipsburg, Pa., March 17.

## Deaths and Obituaries.

**Albert C. Corr, M.D.** Chicago Medical College, 1868, one of the best-known practitioners of Central Illinois, formerly president of the State Board of Health, and president of the Illinois State Medical Society in 1896, died at his home in Carlinville, April 2, after a short illness, aged 63. He was a member of the American Medical Association, and at the time of his death was in editorial charge of the eye and ear department of the *Journal of the Southern Illinois Medical Society*. The following are the resolutions of respect adopted by the Macoupin County Medical Society at the A. C. Corr memorial held in Carlinville, April 4:

Whereas, In obedience to Nature's fixed and unalterable law of life and death, we must part from A. C. Corr, the nestor of our society, a charter member and one of its constant supporters, more than twenty-five years its secretary. Resolved, That we mourn his loss as a brother physician, cut down while in active work for the cause of science and humanity. Resolved, That we escort him to his last resting place, to await the coming of the Great Physician, whose touch healeth all sorrow and pain. Resolved, That a suitable floral emblem be placed upon his bier, as a public testimonial of our appreciation of his beautiful character as a friend, counsellor and Christian gentleman. Resolved, That a copy of these resolutions be made of record and a copy be sent to the bereaved wife and partner. Resolved, That a copy be sent to the city papers and to the state and national medical journals.

**William S. Muir, M.D.**—By the death of Dr. Muir, of Truro, Nova Scotia, Canada has lost one of her foremost general practitioners, and certainly one of the most popular men in the medical profession. Dr. Muir, who was the son of a doctor, was born at Truro in 1853. He was graduated in 1874 from the Halifax Medical College and from Dalhousie University. For a time he served as house surgeon in the Halifax General Hospital, now the Victoria General Hospital, and subsequently took a course in the old country in 1877, again in 1879 and yet again in 1891. He has always been a very active man in medical society work. Elected secretary of the Nova Scotia Medical Society in 1887, he continued to hold that office until the time of his death. Last year he was president of the Maritime Medical Association. For years he has been a prominent and regular attendant at the meetings of the Canadian Medical Association, having held the offices of local secretary and vice-president for the province of Nova Scotia on different occasions. He was a great worker on committees at the annual meetings of the national association, and his loss will be very great indeed. A big, strong, robust,

Scotch-Canadian, of a kindly and sympathetic nature, and withal a jovial disposition, he has been cut down in the prime of life, after but three days' sickness from appendicitis.

**William D. Middleton, M.D.** Bellevue Hospital Medical College, New York, 1868, one of the most eminent surgeons of the West, professor of surgery and dean of the medical faculty of the State University of Iowa, and surgeon-in-chief of the Chicago, Rock Island and Pacific Railway, died at his home in Davenport, Iowa, April 5, from acute septicemia following a wound received while he was performing an operation. It appears that March 30 Dr. Middleton, assisted by Dr. H. W. Braunlich, operated on a woman suffering from peritonitis, possibly of a streptococcal origin. It is supposed that while tying an artery, Dr. Middleton abraded the thumb of his left hand. The next day he was seized with a chill, which was immediately followed by intense oppression over the chest and high fever. There was no local affection until the fifth day, when the arm became edematous and was lanced. Dr. Braunlich is suffering in the same way, and at this time, April 8, is not expected to recover.

**Delavan Bloodgood, M.D.** Jefferson Medical College, Philadelphia, 1854, medical director, U. S. Navy, retired, died at his home in Brooklyn, N. Y., April 5, from heart disease, aged 70. His first service was on the frigate *Merrimac* on the Pacific station. At the opening of the Civil war he was serving on the *Dacotah* in Hampton Roads. Later he was with Farragut on the Mississippi and afterward saw duty off the Newfoundland banks in pursuing privateers. After the war he served on foreign stations, and for several years was fleet surgeon of the Pacific squadron.

**John J. Stafford, M.D.** University of Georgetown, D. C., 1885, a practitioner of Washington, D. C., for several years professor of chemistry at the Georgetown University Medical School, and a member of the American Medical Association, died at his home in Washington, March 17, from chronic nephritis, after a long illness, aged 52.

**Gerald D. O'Farrell, M.D.** University of Pennsylvania, 1862, a prominent practitioner of Philadelphia, who served throughout the Civil war as surgeon of the 63d and 215th Pennsylvania regiments, and afterward settled in Kensington, died suddenly from heart disease while making a professional call, March 27, aged 70.

**Frank L. Portzer, M.D.** Western Pennsylvania Medical College, Pittsburg, 1888, of Greensburg, Pa., a member of the American Medical Association, was found dead in bed from internal hemorrhage, in Saltsburg, March 27, aged 35. He had been in impaired health for a long time.

**Frank Harold Thompson, M.D.** Trinity Medical College, Toronto, Ontario, a well-known young physician, who had spent the last two years as surgeon of the coast and geodetic survey steamer *Patterson*, died from typhoid fever after a long illness, March 21, aged 26.

**D. A. Lewis, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1880, prominent as a physician in Boone County, Neb., until two years ago, when failing health necessitated his retirement, died at his residence in Albion, March 28, from paresis, aged 54.

**William H. H. Nash, M.D.** Miami Medical College, Cincinnati, 1872, a member of the American Medical Association and a practitioner of medicine in Columbus for many years, died from paralysis at the Home for the Aged, Columbus, March 31, aged 65.

**Moses T. Babcock, M.D.** Geneva (N. Y.) Medical College, 1852, who had practiced medicine in Hammondsport, N. Y., for fifty years, died suddenly at his home in that place, March 31, aged 77. During the Civil war he served as assistant surgeon.

**Charles R. Burks, M.D.** Jefferson Medical College, Philadelphia, 1858, a practitioner of Kerr's Creek and Natural Bridge districts, Virginia, died at his home near Sherwood, Rockbridge County, March 26, from consumption, aged 70.

**Thomas Dunn English, M.D.** University of Pennsylvania, Philadelphia, 1839, but who preferred literary to professional pursuits and is best-known as the author of "Ben Bolt," died at his home in Newark, N. J., April 1, aged 82.

**Frederic Augustus Putnam, M.D.** Castleton Medical College, Vt., 1837, who practiced for sixty years in New York City, but had resided at Sutton, Mass., for the past six years, died at his home in that place, March 27, aged 89.

**Charles L. Tarleton, M.D.** Tulane University, New Orleans, La., a prominent physician of Callaway County, Mo., and a member of the state pension board, died from Bright's disease at his home in Cedar City, aged 66.

**Harry W. Whitesell, M.D.** Western Pennsylvania Medical College, Pittsburg, Pa., 1897, of Sewickley, Pa., was found dead on a pile of rocks on the banks of the Ohio, March 23. He was 28 years of age.

**David J. Underwood, M.D.** College of Physicians and Surgeons, Baltimore, 1887, a leading physician of New Martinsville, W. Va., died suddenly at his home in that place, March 26.

**Gilbert P. Mills, M.D.** Bellevue Hospital Medical College, New York, 1892, died at his ranch home near Missoula, Mont., March 26, from consumption, after an illness of several years.

**James Watt Taylor, M.D.** Medico-Chirurgical College, Philadelphia, 1866, a practitioner of Pittsburg, Pa., died at his residence, March 18, after an illness of four years, aged 72.

**Thomas N. Bryan, M.D.** University of Louisville, 1857, for many years a prominent physician of Indianapolis, died at his home in that city, April 3, after an illness of one week.

**Simon P. Breed, M.D.** McDowell Medical College, St. Louis, Mo., 1847; University of Pennsylvania, Philadelphia, 1865, died at his home in Princeton, Ill., March 21, aged 83.

**S. Townsend Bowne, M.D.** Albany (N. Y.) Medical College, 1872, for several years a prominent physician of Leadville, Colo., died from dementia at Pueblo, March 26.

**Jacob Young, M.D.** Baltimore Medical College, 1843, the oldest physician in Wetzel County, W. Va., died at his home in New Martinsville, March 22, aged 82.

**Bowen Combs Howell, M.D.**, who had practiced medicine in La Porte County, Ind., for more than fifty years, died at his home in La Porte, March 29, aged 82.

**Jerome F. Hertzmann, M.D.** a resident of Omaha for twenty-five years, died at his home in that city, March 28, after an illness of seven months, aged 48.

**Sven S. Reimestad, M.D.** University of Minnesota, 1895, a practitioner of Madelia, Minn., died suddenly, March 29, at a hospital in Minneapolis, aged 30.

**Richard H. Sommerville, M.D.**, a native of Moorefield, W. Va., a graduate of the University of Maryland, 1882, died at San Antonio, Texas, aged 40.

**Charles F. Ulmer, M.D.** Arkansas University, Little Rock, 1895, a practicing physician of Dublin, Texas, died at his home in that city, March 23, aged 45.

**Oscar K. Guyer, M.D.** Medical College of Ohio, Cincinnati, 1884, a prominent practitioner of Lewisville, Ind., died at his home in that place, March 31.

**John F. Ely, M.D.** formerly of Cedar Rapids, Iowa, and one of the founders of the Dubuque Medical Society, died in California, March 14, aged 81.

**E. E. Furber, M.D.** Harvard University Medical School, Boston, died at his home in Springfield, Vt., March 22, from pneumonia, aged 34.

**Manning T. Smith, M.D.** University of Maryland, Baltimore, 1881, died at his home in Union, S. C., March 25, from pneumonia, aged 47.

**Robert P. Davis, M.D.** Cincinnati College of Medicine and Surgery, 1873, died at his home in Portland, Ind., March 28.

**Alfred J. Sporry, M.D.** University of Zurich, Switzerland, 1885, died at Portland, Ore., March 16.

## Association News.

### Annual Announcement.

The fifty-third annual session (55th year) of the American Medical Association will be held at Saratoga Springs, N. Y., on Tuesday, Wednesday, Thursday and Friday, June 10, 11, 12 and 13.

#### GENERAL MEETING.

The first general, or opening meeting of the Association will be called to order at 11 a. m., Tuesday morning, June 10.

#### MEMBERSHIP.

No permanent member shall take part in the proceedings of the Association, or of any of its Sections, until he has exhibited his credentials to the proper officer or committee, entered his name and address in full on the registration book, and paid his annual dues. He shall also indicate the Section to which he will officially attach himself.

Permanent members who have complied with the foregoing regulations shall at all times be entitled to attend the General Meetings and Sections, and to participate in the affairs of the

Association, so long as they continue to conform to its regulations.

No individual who shall be under sentence of expulsion or suspension from an affiliated society (whether a directly affiliated state or territorial society or an indirectly affiliated local society) of which he may have been a member, or whose name shall have been dropped from the rolls of the same, shall be received as a member or shall be allowed to continue as a member of this Association, until he shall have been relieved from said sentence or disability by such society; nor shall any person not a member of his local affiliated medical society, provided there be such a one, be eligible to membership or be allowed to continue as a member in the American Medical Association.

Members may vote for Section officers only in that Section with which, upon registration, they have declared their intention of uniting.

Any permanent member who shall fail to pay his annual dues for one year, unless absent from the country, shall be dropped from the roll of permanent members, after having been notified by the secretary of the forfeiture of his membership.

Honorary Members may be elected by the House of Delegates on the nomination of a Section, but not more than three Honorary Members shall be elected in any one year.

Honorary and Associate Members shall have all the rights of membership except those of voting and holding office. They shall not be assessed for dues, nor shall they be entitled to receive THE JOURNAL free.—From Chapter I of By-laws.

#### HOUSE OF DELEGATES.

The House of Delegates will convene for its first meeting at 2 p. m., Tuesday, June 10.

Each state and territorial society entitled to representation shall have the privilege of sending to the House of Delegates one delegate for every 500 of its resident regular members, and one for any additional fraction of that number; but each affiliated state and territorial society shall be entitled to at least one delegate.—Chapter III, Sec. 2, By-laws.

Members of the House of Delegates shall be elected for a term of two years, and those state and territorial societies entitled to more than one representative are requested so to arrange such election that one-half of their delegates, as near as may be, shall be elected each year.—Chapter III, Sec. 4, By-laws.

According to reports received March 1, 1902, the following is the number of members in the various state societies and the number of delegates to which each was entitled at that time: Alabama, membership 1156, delegates, 3; Arizona, 87, 1; Arkansas, 270, 1; California, 315, 1; Colorado, 326, 1; Connecticut, 684, 2; Delaware, 119, 1; District of Columbia, 394, 1; Florida, 160, 1; Georgia, 650, 2; Idaho, 75, 1; Illinois, 1203, 3; Indian Territory, no response, but will be entitled to only 1 delegate; Indiana, 1625, 4; Iowa, 719, 2; Kansas, 109, 1; Kentucky, 550, 2; Louisiana, 316, 1; Maine, 445, 1; Maryland, 678, 2; Massachusetts, 2644, 6; Michigan, 606, 2; Minnesota, 466, 1; Mississippi, 314, 1; Missouri, 270, 1; Montana, 113, 1; Nebraska, 410, 1; New Hampshire, 365, 1; New Jersey, 1038, 3; New Mexico, 42, 1; New York, 1421, 1; Nevada, no response, but will be entitled to only 1 delegate; North Carolina, 485, 1; North Dakota, 126, 1; Ohio, 989, 2; Oklahoma, 145, 1; Oregon, 212, 1; Pennsylvania, 3518, 8; Rhode Island, 251, 1; South Carolina, no response, but will be entitled to only 1 delegate; South Dakota, 68, 1; Tennessee, 317, 1; Texas, 352, 1; Utah, 87, 1; Vermont, 193, 1; Virginia, 1033, 3; Washington, 156, 1; West Virginia, 306, 1; Wisconsin, 628, 2; Wyoming, 37, 1.

#### THE SECTIONS.

The various scientific Sections of the Association will hold their first meetings at 2 p. m., Tuesday, June 10. Section 2 of Chapter IX of the By-laws says that the Sections shall be composed of those who have complied with Sections 1 to 4 of Chapter I of the By-laws. These are as follows:

**Permanent Members.**—Permanent Members shall consist of such members of the state societies, together with their affiliated local societies, entitled to representation in this Association as shall make application for admission, in writing to the Treasurer, and accompany said application with a certificate of good standing signed by the president and secretary of the society of which they are members, and the annual fee.

**Members by Invitation.**—Members by Invitation shall consist of distinguished physicians of foreign countries who may be invited by the officers of Sections or of the Association. They shall hold their connection with this Association until the close

of the annual session to which they are invited, and shall be entitled to participate in all of its affairs, as in the case of permanent members, but they shall not be assessed the annual dues.

**Honorary Members.**—Honorary Members shall be physicians of foreign countries who have risen to pre-eminence in the profession of medicine.

**Associate Members.**—Representative teachers and students of the allied sciences, not physicians, may become Associate Members by the vote of the House of Delegates.

#### PAPERS BEFORE SECTIONS.

It shall be the duty of every member of the Association who proposes to present a paper or report before a Section to forward either the paper or an abstract indicative of its contents, and its *length*, to the Secretary of such Section at least one month before the annual session at which the paper or report is to be presented. This abstract shall contain not less than fifty nor more than two hundred words.

#### ORATIONS.

The following annual orations will be delivered: On Medicine, Dr. Frank Billings, Chicago; on Surgery, Dr. Harry M. Sherman, San Francisco, Cal.; on State Medicine, Dr. J. M. Emmert, Atlantic, Iowa.

#### ARRANGEMENTS.

Chairman Committee of Arrangements, Dr. Geo. F. Comstock, Saratoga Springs, N. Y.

#### PROPOSED AMENDMENTS.

Amendment to the Constitution and By-laws, offered by Dr. L. B. Tuckerman, of Ohio: Amend Section 3, Chapter VII of the By-laws by substituting the following:

"Section 3. Committee on Legislation. The Committee on Legislation shall consist of three members appointed by the President of the Association for a term of three years. One member shall be a resident of Washington, D. C., one of Baltimore, and one of Philadelphia. It shall be the duty of the Committee to represent before Congress the wishes of this Association regarding any proposed legislation that in any respect bears upon the promotion and preservation of the public health or upon the material or moral welfare of the medical profession. This Committee shall also invite to a conference once a year or oftener if need be, one delegate each from the medical service of the United States army, the United States navy, and the Marine-Hospital Service, one from the Bureau of Animal Industry, and one from each affiliated state or territorial medical society; such conference to meet in Washington to consider questions of medical and sanitary legislation, and to report back to this Association and to the several state and territorial societies."

Amendment to the Constitution and By-laws, offered by Dr. T. J. Happel, of Tennessee:

Chapter IX, Section 7, as follows: Strike out the following words of Section 7, Chapter IX, "reprints and transactions of Sections, including its lists of members, its rules of order, its lists of officers, as now published, shall be paid for out of the funds of the Association, and furnished free to members of the Association."

#### OFFICERS OF SECTIONS, 1901-1902.

**Practice of Medicine**—Chairman, Frank A. Jones, Memphis, Tenn.; Secretary, Robert B. Preble, Chicago.

**Obstetrics and Diseases of Women**—Chairman, J. H. Carstens, Detroit; Secretary, C. L. Bonifield, Cincinnati.

**Surgery and Anatomy**—Chairman, DeForest Willard, Philadelphia; Secretary, James B. Bullitt, Louisville.

**Hygiene and Sanitary Science**—Chairman, Arthur R. Reynolds, Chicago; Secretary, H. M. Bracken, Minneapolis, Minn.

**Ophthalmology**—Chairman, Frank Allport, Chicago; Secretary, C. A. Veasey, Philadelphia.

**Diseases of Children**—Chairman, H. M. McManahan, Omaha, Neb.; Secretary, Frank X. Walls, Chicago.

**Stomatology**—Chairman, A. H. Peck, Chicago; Secretary, Eugene S. Talbot, Chicago.

**Nervous and Mental Diseases**—Chairman, Richard Dewey, Wauwatosa, Wis.; Secretary, F. Savary Pearce, Philadelphia.

**Cutaneous Medicine and Surgery**—Chairman, Henry W. Stelwagon, Philadelphia; Secretary, R. R. Campbell, Chicago.

Haynes, vice-president, and Dr. William H. Deaderick, Marianna, secretary and treasurer.

**Dearborn County (Ind.) Medical Society.**—At the annual meeting of this Society, held March 26, at Lawrenceburg, Dr. O. P. M. Ford, Rising Sun, was elected president; Dr. Richard C. Bond, Aurora, vice-president, and Dr. Francis M. Mueller, Lawrenceburg, secretary.

**Smith County (Texas) Medical Society.**—The physicians of Smith County met at Tyler, March 24, and organized a county medical society, with Dr. Thomas J. Bell, Tyler, president; Dr. William S. Lacey, Troupe, vice-president, and Dr. Albert Woldert, Tyler, secretary and treasurer.

**Montgomery County (Ind.) Medical Society.**—At the annual meeting of this Society, held in Crawfordsville, March 26, Dr. Harry E. Greene, Crawfordsville, was elected president; Dr. George T. Williams, Brown's Valley, vice-president; Dr. Effie Current, secretary, and Dr. Oliver H. Jones, Crawfordsville, treasurer.

**Jefferson County (W. Va.) Medical Society.**—This Society was reorganized, March 15, at Charlestown, W. Va., and the following officers elected: Dr. William Neill, Charlestown, president; Drs. J. M. Miller, Charlestown, and Charles C. Lucas, Kearneysville, vice-presidents; Dr. George A. Davis, Summit Point, secretary, and Dr. William E. Perry, Halftown, treasurer.

**North Central Ohio Medical Society.**—The twenty-first annual meeting of this Society was held in Mansfield, March 28, at which the following officers were elected: Dr. Josiah S. Hedges, Mansfield, president; Drs. A. Melville Crane, Marion, and S. N. Alban, Mansfield, vice-presidents; Dr. John McG. Burns, Mansfield, secretary, and Dr. J. Lillian W. McBride, Mansfield, treasurer.

**American Association of Pathologists and Bacteriologists.**—This Association held its second annual meeting at Cleveland, Ohio, March 28 and 29. The following officers were elected for the ensuing year: President, Dr. Ludvig Hektoen, Chicago; vice-president, Dr. J. Ewing, New York City; secretary, Dr. H. C. Ernst, Boston, Mass., and treasurer, Dr. Eugene Hodenpyl, New York City.

## Societies.

## COMING MEETINGS.

American Medical Association, Saratoga Springs, N. Y., June 10 to 13.

Medical Association of the State of Alabama, Birmingham, April 15, 1902.

Medical Society of the State of California, San Francisco, April 15-17, 1902.

Medical Association of Georgia, Savannah, April 16, 1902.

Mississippi State Medical Association, Jackson, April 16, 1902.

New Mexico Medical Society, Albuquerque, April 16, 1902.

South Carolina Medical Association, Spartanburg, April 16-17, 1902.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.

Association of American Physicians, Washington, D. C., April 29 to May 1, 1902.

American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.

International Association of Railway Surgeons, St. Louis, Mo., April 30 and May 1 and 2, 1902.

American Gastro-Enterological Association, Washington, D. C., May 2, 1902.

Nebraska State Medical Society, Omaha, May 6-8, 1902.

Texas State Medical Association, Dallas, May 6-9, 1902.

Kansas Medical Society, Lawrence, May 7-9, 1902.

American Therapeutic Society, New York City, May 13, 1902.

Utah State Medical Society, Salt Lake City, May 13-14, 1902.

Oklahoma Territory Medical Association, Oklahoma City, May 14, 1902.

Arkansas Medical Society, Little Rock, May 13-15, 1902.

New Hampshire Medical Society, Concord, May 15-16, 1902.

Illinois State Medical Society, Quincy, May 20-22, 1902.

American Surgical Association, Albany, N. Y., May 20-22, 1902.

Medical Association of the State of Missouri, St. Joseph, May 20-22, 1902.

Kentucky State Medical Society, Paducah, May 7-9, 1902.

Arizona Medical Association, Tucson, May 21-22, 1902.

Medical Society of West Virginia, Parkersburg, May 21-23, 1902.

Medical Association of Montana, Anaconda, May 21-22, 1902.

Iowa State Medical Society, Des Moines, May 21-23, 1902.

Indiana State Medical Society, Evansville, May 22-23, 1902.

American Pediatric Society, Boston, May 26-28, 1902.

American Laryngological Association, Boston, Mass., May 26-28, 1902.

American Gynecological Society, Atlantic City, May 27, 1902.

Connecticut Medical Society, New Haven, May 28-29, 1902.

Ohio State Medical Society, Toledo, May 28-30, 1902.

**Erie County (N. Y.) Medical Association.**—At the annual meeting of this Association, Dr. James Grosvenor was elected president; Dr. Jacob S. Otto, secretary, and Dr. William I. Thornton, treasurer, all of Buffalo.

**Lee County (Ark.) Medical Society.**—The physicians of Lee County, Ark., have organized this Society with Dr. T. J. Robinson, Marianna, president; Dr. William S. Bradford,

## CHICAGO MEDICAL SOCIETY AND CHICAGO SURGICAL SOCIETY.

*Joint Meeting, held March 5, 1902.*

Dr. A. H. Ferguson in the Chair.

## Cholelithiasis.

The first paper, "Medical Aspect of Cholelithiasis," by Dr. Robert B. Preble, appears in this issue, page 938.

DR. WILLIAM J. MAYO, Rochester, Minn., read a paper (by invitation) entitled, "An Analysis of 328 Operations Upon the Gall-Bladder and Bile Passages." A study of these cases brings out some general features of interest. The origin was benign in 311 and the number of deaths was 8, giving a mortality of about 2.5 per cent. In 17 for malignant disease, there were 3 deaths, a mortality of 18 per cent. In 214 cases, the stones were located in the gall-bladder or cystic duct or both, with 2 deaths. In about 10 per cent. of these cases stones were contained in the cystic duct. The after history of many of these cases, in which the cystic duct was involved and simple cholecystostomy performed, was not wholly favorable and for cases in which this duct has been obstructed or in which stones have been lodged in the duct for a length of time, cholecystostomy is insufficient, and the gall-bladder should be extirpated at the primary operation if the patient is otherwise in good condition.

Stones in the cystic duct are often more easy to remove with the gall-bladder than without it. If the peritoneum binding it to the liver be divided on each side, the connective-tissue between can be easily separated with the finger and by using the gall-bladder as a tractor, and if necessary, dividing the peritoneal and muscular coats just above the cystic duct, the mucous tube of the latter will strip out readily, bringing the stone with it. The mucous coat about the neck of the gall-bladder is thick and separates easily from the outer coats, while the fixation by adhesions is to the outer coats alone. At the fundus, the mucous membrane is less easy to separate and a combination of amputation of the fundus with removal of the mucous coat from the lower portion of the gall-bladder and

cystic duct, makes cholecystectomy a safe operation. A study of these cases leads to the belief that stones passing by ulceration and perforation from the bile tract to the intestine do so slowly and that cicatrization usually takes place behind, before the extrusion into the intestine is accomplished.

The cases of cholecystitis numbered 34, with 5 deaths. This mortality calls attention at once to the serious nature of the infections. All cases in which an acute suppuration existed at the time of the operation, with or without stones, and all cases in which the gall-bladder was found thickened and contained more or less ropy mucus and bile or sand-like sediment, without stones, were classified at the time of operation as cholecystitis. The author has long held the view that the dependent fundus was a mechanical factor which rendered the possibility of stone formation in cases in which the stagnation of the bile, infection of the gall-bladder and obstruction at the cystic duct were the other factors, that is to say, if the cystic duct were the bottom, the sediment would pass out first. In 31 cases, stones were found in the common duct with one death. In only one case was it possible to remove the stone through the cystic duct by dilating it. In 29 cases, the duct was incised and the stones removed. In 5 cases this was accomplished by separating the gall-bladder from the liver and incising the free surface down to and along the cystic duct to the common duct and the latter was incised at the juncture.

Jaundice in connection with stones in the common duct was a most variable feature. In many cases it was so slight as not to attract especial attention and the finding of stones in the common duct was a surprise. In the majority the jaundice was marked. One case of extreme jaundice, from a stone impacted in the cystic duct at its juncture with the common duct, and three cases of jaundice from malignant disease died from post-operative capillary oozing. In all of these cases there were subcutaneous ecchymotic spots, looking like purpura hemorrhagica before operation. Every case of jaundice with this condition died in this way. No case in which this was not present died from this cause, although several were in extreme jeopardy.

Cholecyst-enterostomy was performed three times for chronic pancreatitis and three times for malignant disease. The anastomosis was made to the duodenum twice and to the transverse colon four times. So far as we could judge, the anastomosis with the colon answered every purpose. Malignant disease, involving the bile tract, was found seventeen times; the results were very discouraging.

#### Diagnosis of Gallstones.

DR. FRANK BILLINGS said the diagnosis was helped somewhat by a knowledge of conditions which led to gallstones. For instance, knowledge that an individual had suffered from typhoid fever, chronic or infective gastro-intestinal disease, colon bacillus infection of other parts of the body and of the gall tract, pneumonia or possibly colonic infection, would help in making the diagnosis. The age of the patient, if the diagnosis was doubtful, would be of considerable aid. Gallstones rarely occur before adult life, but with increasing frequency after that period. They occur oftener in the female than in the male, because of the former's manner of dress and more sedentary life. Courvoisier, quoted by Osler, states that 25 per cent. of all women over 50 years of age have gallstones. The previous condition of health should be duly considered. Stones remain in a latent condition for a considerable time in some cases without causing symptoms, or so slight are the symptoms as to be attributed to something else, and not until some accidents due to gallstones occur are we led to the correct diagnosis. A large percentage of people die of some other disease and gallstones are found postmortem.

Pain was usually present in cases of stones, but cases occurred without pain. When pain was present it was usually different from pain of almost every other kind, and severe, considering the small part of the body that was involved. Perhaps a small stone causes a more severe pain than a larger one. The pain from stones in the cystic duct was much less than that from the same in the common duct. With stones in the cystic duct, the pain radiated, as a rule, to the right side, and was often felt in the region of the shoulder-blade. Pain from the common duct was more severe and radiated

from just above the umbilicus downward and to the left, and might encircle the body in the region of the costal arch. Pain was accompanied, as a rule, with disturbance of the gastro-intestinal tract; nausea, vomiting and, if the common duct was not obstructed, vomiting went on until bile was vomited, the presence of bile in the vomit was good evidence that the common duct was not completely, if at all, obstructed.

The next important and common symptom was jaundice; it did not occur in uncomplicated cases. Dr. Preble had already gone over some of the differential diagnostic points. There were some others that might be mentioned, for instance, confounding gallstones with floating kidney. Women were sometimes seized with a sudden attack of pain, more often on the right than left side, sometimes associated with jaundice, and a recognition of floating kidney, its replacement, etc., would enable one to differentiate it from gallstones. Gumma of the liver was usually multiple, associated with a remittent type of fever, but it was not always multiple. It was possible for it to be situated near the gall-bladder, and cause symptoms similar to those of gallstones. He had seen two such cases, in both of which a diagnosis of gallstones was made.

Dr. Billings then quoted at length the statistics of gallstones as found in the literature, the number that had been seen and operated by different surgeons, the results, mortality, etc.

#### Indications for Surgical Intervention.

DR. ARTHUR DEAN BEVAN said that he could not agree with those surgeons who say that whenever a diagnosis of gallstones is made a surgical operation is indicated. In his own dissecting room experience during a large number of years, 16 per cent. of cases had stones, and he thought it would be safe to say that from 8 to 10 per cent. of the adult population in most communities had gallstones. Taking this approximate estimate, it led to the conclusion that in a great number of cases the gallstones were innocuous.

With the very brilliant results that had been obtained by surgical treatment, with the very low mortality resulting from it in expert hands, the indications for operation were very much wider than they ever had been. These indications he summarized as follows: 1, cases in which there is obstruction of the cystic duct, either the direct or indirect result of gallstones; 2, cases of obstruction, the direct or indirect result of continuous or intermittent attacks; 3, cases of perforative inflammation of any part of the bile tracts, including the gall-bladder.

This leaves a great group of cases without symptoms of obstruction or a perforative inflammation, but symptoms in the majority of cases of stones remaining in the gall-bladder. Such cases go from physician to physician, many of them diagnosed as cases of dyspepsia or gastric neuralgia. Medical men were beginning to recognize this class of cases and recommend surgical intervention more frequently now than formerly. Another group was where the patients had gallstones, probably recognized, but in whom the attacks were infrequent. These cases required the combined judgment of the internist and surgeon as to the desirability of surgical intervention.

#### Real and Apparent Recurrences After Operation.

DR. E. WYLLYS ANDREWS discussed this question. Do gallstones ever reproduce themselves after operation, or, does the removal of gallstones fail to cure the patient who has them? These were two very different questions in the last analysis and might require opposite answers. Often the condition may not be new stones in the bladder or ducts, but old ones purposely or accidentally left or else kinking of the cystic duct, stenosis from carcinoma, adhesions, or other mechanical cause for hydrops of the gall-bladder. But of apparent recurrences numerous instances did occur. Formerly he thought and taught that gallstones would reproduce *a priori* as urinary bladder and kidney calculi were known to do. After reading the positive statements of Courvoisier, Riedel, Kehr, and others, he searched carefully in his records and could not find one unmistakable case of stone reproduction, i. e., one in which an overlooked stone, ulcer or cancer of the gall tracts,

old adhesions, or some other cause might not explain the recurrence of symptoms. Riedel says that gallstone reproduction does not occur because the drainage cures the gall-bladder inflammation and stops their formation. Even if a few are left, they come out on the dressings. Dr. Andrews thought this was bad teaching if it led to superficial work. It was the exact opposite of what Dr. Fenger's example would lead to. It also took no account of choledochous stones which never would come out if left alone. Riedel also states that he has operated twelve years on gallstones, and never had a real reproduction of stones. Kehr in one thousand cases of his own and Riedel had no proved case of reproduction. He thinks gallstone reproduction is an occurrence usually which takes place once in a lifetime.

Leaving out of account diseases of neighboring parts, such as the kidney, ureter, cecum or appendix, all of which might give pain like hepatic colic, there was quite a list of post-operative troubles of the gall tracts themselves which we were powerless to prevent and which might defeat all efforts at relief. Among these were adhesions to viscera and anterior wall; hernia in drainage scar; cholecystitis, still uncured; stones accidentally left and stones knowingly left. Stones were very unsatisfactorily felt when the gall-bladder was not opened. Those surgeons, who did the two step operation, often knew very little of how many should come out later. There always would be a few cases to be operated on in the most conservative and rapid manner, and with a minimum of anesthetic or local anesthesia. The aim in doing an incomplete operation was to relieve the cholemia and later complete the operation. Stones intentionally left were not recurrences; stones accidentally left were, it was to be hoped, less common than at first. He would state it as his observation that this had occurred oftener in the past than some operators would lead one to think. As he looked back on his earliest work, before the common duct operation was elaborated by Fenger, he could think of several cases lost through inefficient search, and the now discredited idea of crushing stones through the duct wall. Some of these continued to have jaundice after the gall-bladder had been cleared of numerous stones.

It was unfair to demand more of surgeons than a good majority of cures. Internists with the Carlsbad cure only succeeded in reducing the stones to a quiescent or sleeping state. We did not in any operation get a uniform series of cures, but this did not discredit the operation. The only thing which could discredit any operation was a failure to report bad as well as good results, so that false statistics gained currency.

The treatment of complications causing recurrence of gallstone symptoms was often satisfactory from a surgical standpoint. An overlooked carcinoma might be detected at a later exploration. Stones purposely or accidentally allowed to remain might be taken out after the patient had been built up by drainage. Adherent bands might be divided to release the gall-bladder, but broad adhesions were difficult to remove. A puncture might be made in a bladder once drained through the old adhesion with little or no danger. Finally, cholecystectomy, as advised by William J. Mayo, Lobker, Kehr, Langenbuch and Korte, was an admirable cure for some of the unpleasant sequelae of gallstone work.

#### Relation of Gallstones to Fat Necrosis.

DR. WILLIAM A. EVANS discussed the anatomic connection between the bile ducts and the pancreatic ducts and said the wonder is not that there should be a relation between disease processes situated in these two structures, but that that relation is not more apparent than it is. Stones passing down the bile ducts are prone to locate at various points in those ducts, and the results that ensue depend in a measure upon the location of the stones. He mentioned four cases of fat necrosis which he had collected up to last summer accompanied, and perhaps caused, by gallstones, and said that in not one of them, so far as he was able to demonstrate, was there stone obstruction at the time of death. Since last summer he had knowledge of eight cases of fat necrosis in this vicinity associated with gallstones. In most of the cases he had seen there was a history of repeated attacks of gallstone colic. In three cases the attacks began much as did the others, but the

patients, instead of getting well after the stones had passed, continued to suffer. The pain and tenderness were irregular in their distribution, in one case shifting around the abdomen in a rather peculiar fashion. The sense of discomfort and uneasiness was rather more marked than the pain. Another marked symptom was a cyanosis that amounted to lividity. Neither the fever, pulse nor respiration was very suggestive. Abdominal inspection postmortem and operative, showed the changes to be those of fat necrosis. None was hemorrhagic in type. None showed much digestion of proteids. In two of the cases that came to autopsy the liver, duodenum, stomach and pancreas were removed en masse, and the ducts were carefully searched. They were radically examined in two other cases. In none was obstruction to the common or the pancreatic duct found. He thinks that old gallstone cases are liable to eventuate in fat necrosis.

DR. MAYO, in closing, stated that uncomplicated cases of gallstone disease gave a very small mortality. Considering the low mortality of early operation, he believes it will only be a short time when internists will send their gallstone patients to surgeons as promptly as they now send them their cases of chronic appendicitis.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

*Regular Meeting, held March 17, 1902.*

President, Dr. Parker Syme, in the Chair.

#### Smallpox and Its Differentiation.

DR. CHARLES S. BENEDICT read the opening paper in the symposium on smallpox. He said that so anxious were many persons to call smallpox by some other name and thus conceal its true nature that it was not uncommon at the present time to meet with it under such names as "Cuban itch" and "Philippine measles." Varioloid was not recognized officially by the health department for it was nothing more than a very mild type of smallpox, demanding the same isolation and care. The presence of a rigor, followed by high fever, headache, angina, lumbar pain and prostration should be sufficient to lead the physician to search for an eruption. The initial fever often felt suddenly by crisis and the secondary fever might be as severe as that of the first stage. The eruption of smallpox ordinarily made its appearance in from 24 to 36 hours after the chill, was at first macular and was completely out in about 24 hours. The macules were dark red and disappeared on pressure. They were followed in a few hours by the characteristically hard, shot-like papules, which were converted into vesicles by the sixth day, and into pustules by the ninth day. The hemorrhagic form of smallpox terminated fatally within forty-eight hours. Smallpox should be differentiated from varicella, measles, scarlatina, malignant endocarditis, cerebrospinal meningitis, erythema multiforme, papular syphilides and pemphigus. In varicella there was not the hard papule of smallpox and umbilication was rare. In measles no vesicles would be observed in the throat. Scarlet fever might be confounded with variola in the earliest stage of that disease only, but the erythema of variola was ephemeral except in the hemorrhagic form, and did not disappear on pressure. In the hemorrhagic form the mucous membranes were apt to bleed, which was not the case in scarlet fever. The petechial rash associated with malignant endocarditis was more likely to be mistaken for typhus fever than smallpox. Heart murmurs would not aid in the differentiation, but the duration and course of the disease would do so. The appearance presented by pemphigus and the absence of constitutional symptoms should serve to readily differentiate it from variola. Of course, the lesions of vaccinia very closely resembled those of variola, but the lesions were much more scanty and the duration of the disease was limited to nine days. In the early diagnosis of smallpox no one symptom or sign should be relied on implicitly.

#### Smallpox and Its Treatment.

DR. S. DANA HUBBARD was the author of this paper. He insisted that the surroundings of the smallpox patient should be as nearly aseptic as possible and, while the sick room or ward should be kept at a temperature of 70 to 78 F. and be

well ventilated, draughts of air should be carefully avoided, as the mucous membranes are exceedingly sensitive and pneumonia in such persons is very fatal. The attendants and visitors should wear large, loose gowns, rubber shoes, gloves and caps and these should be discarded in an anteroom. After the removal of the patient, the fumigation of the room should be conducted so thoroughly that at its completion the fumes would be so dense as to prevent one seeing through them for more than four feet. The smallpox patient and his surroundings must be kept scrupulously clean, the patient himself receiving a daily bath or sponging. After the bath the application of alcohol was grateful to the patient, but if there was much itching 5 to 20 per cent. carbolic oil should be used. During the stage of suppuration the water of the bath should contain from half a grain to two grains of permanganate of potassium to the ounce and the patient should be given quinin internally, though unusually small doses, because of the peculiar susceptibility to quinin exhibited by this class of persons. In septic cases alcoholic stimulants should be given very freely, remembering the injunction of a well-known physician, "Don't let them die sober." During the vesicular and pustular stages it was desirable to prevent rupture of the lesions. He thought if outside infection could be prevented pitting would not occur, nevertheless but little progress had been made in this important part of the management of smallpox cases. The too early removal of the scabs should be prevented. A mixture of boric acid and glycerin, applied constantly under a mask, he had found to act very well. The patient should be very thoroughly scrubbed and scraped and bathed in bichlorid solution before being discharged.

#### What Constitutes Efficient Vaccination?

DR. FRANK S. FIELDER read this paper. In answer to the important question propounded in its title, he defined efficient vaccination as that which secures to those vaccinated, 1, the smallest proportion of smallpox cases per thousand individuals; 2, the longest duration of immunity among those who finally take smallpox; 3, the lowest mortality among those who contract the disease, and 4, the mildest course of the disease and the least amount of subsequent pitting in those who survive it. A good vaccination scar is whiter than the surrounding skin, having a regular and well-defined outline and a depressed and sometimes slightly striated center surrounded by a foveated ring. The latter corresponded to the area of active vesiculation, and the center represented either the original area of scarification or a cicatrix following the separation of a more or less deep central slough. The size of the scar depends partly upon the scarification and partly on the activity of the virus. Occasionally there would result a poor scar from a vaccination running a typical course, but the rule was that a good vaccination yields a good scar. Dr. Fielder then quoted at length from foreign statistics bearing on the question as to the number and quality of the vaccination scars and the duration of immunity. Thus observations had been made in London by Dr. E. C. Seaton and Dr. Buchanan in the smallpox epidemic of 1863 on about 50,000 cases. Their tables show that the smallest proportion of smallpox cases per thousand was found in those who had been vaccinated in four or more spots and presented scars of excellent quality. R. Cory, in a series of observations on 448 persons who had had smallpox, came to the conclusion that vaccination by multiple insertion gives slightly longer immunity to smallpox than the one-spot method. J. F. Marson, who for more than thirty years was the resident physician of the London Smallpox Hospital, concludes that the efficiency of the vaccination is in exact ratio to its excellence and completeness, as shown by the number and quality of the resulting scars. W. M. Welch made a similar study of his cases while in charge of the Philadelphia Smallpox Hospital for more than twenty-five years, and concluded that the quality of the scars is a far more reliable indication of the degree of the protection than the quantity and that when the scars are typical it makes no difference whether they are single or multiple. Dr. Fielder closed his paper by accepting Marson's conclusion that "test the question in whichever way we will the result is in favor of producing four vesicles at least at vaccination with lymph which leaves good permanent cicatrices."

DR. JOHN H. BRANTH was of the opinion that some of the great epidemics of smallpox in England and Ireland had been favorably influenced by the process of inoculation and that it was probably safer to perform inoculation at a time when there is no epidemic of smallpox. Some light, he said, might be thrown upon the nature of vaccination by the statement of Ernest Hutchinson, D.V.S., of Portland, Ore., U. S. Inspector of Animal Industry, that the tubercle bacilli from one species can not be transplanted with the same success to other species, and that if successful, a modification of the virulence takes place. It was possible that vaccinia might be due to modified virulence like that claimed by Hutchinson for tuberculosis of different species. It had been contended by the antivaccinationists that compulsory vaccination was an infringement of personal liberty, but to allow an unvaccinated person to remain in our midst and thus menace our well-being was an infringement of our personal liberty.

DR. WILLIAM DOLZ said that he had been engaged in taking care of 1300 cases of smallpox in the province of Santiago, Cuba, and had adopted essentially the treatment outlined by Dr. Hubbard. They had been given a bichlorid of mercury bath, 1 to 5000, once, twice or three times a day, the worse the eruption the more frequent these baths. Half of the cases were confluent, two-thirds not vaccinated and the surroundings most unfavorable. Despite these drawbacks the mortality rate was 10 per cent. These 1300 had been discharged within a period of ten weeks and although for over a year previously an epidemic of smallpox had been raging and had carried off over 4000 people, no new cases had developed in that district in the three years that had elapsed since that time.

DR. DAVID P. AUSTIN was of the opinion that Dr. Fielder's quotations from hospital statistics were misleading because in certain countries it was the rule to make three or four insertions at the primary vaccination, thus vitiating the results of any subsequent investigation into the number of vaccination scars present. Two vaccinations, made at different times, protect better against smallpox than one vaccination consisting of several insertions. At one time he had vaccinated 10 children successfully, and one month later had again successfully vaccinated 8 of these children. At the end of the second month 6 of the children were again successfully vaccinated, and at the end of still another month 6 of the children were vaccinated with 4 successes. One vaccination should not be relied on for any length of time for protection. He had records of 10,000 vaccinations of public school children that he had done and these showed that between 60 and 65 per cent. of these vaccinations had been successful. Of those vaccinated only once before, 40 or 50 per cent. were successful, while there were only about 8 per cent. of successes in those who had been previously vaccinated four or five times. In his opinion, immunity was that condition which protected the person from smallpox for the balance of his life. In some persons, four or five vaccinations were necessary to establish this immunity, but when once secured it lasted for life.

DR. FIELDER, in closing, agreed with Dr. Austin regarding the superior results obtained from repeated vaccination as opposed to simultaneous insertions. That immunity to smallpox and to vaccination are not the same had been demonstrated by a resident physician of the smallpox hospital on North Brother Island. This gentleman, though living in the midst of smallpox and not contracting the disease, was able to successfully vaccinate himself. There was no way of determining how long a time a given individual would remain immune by reason of a vaccination.

#### NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, held March 6, 1902.*

President, Robert F. Weir, in the Chair.

#### The Use of the X-Ray in the Treatment of Some Forms of Cancer.

DR. FRANCIS H. WILLIAMS, Boston, said that it was immaterial whether a static machine with large plates was used or a coil for the generation of the x-ray. There should be an adjustable spark gap and the tube-holder should be so ar-

ranged as to conveniently focus the rays on the part to be treated. For this purpose he was accustomed to make use of a box painted inside with white lead, having an opening in the bottom for the exit of the rays. By means of a suitable lead screen a cone of rays a little larger than the area to be treated was brought to bear on the diseased part. For the treatment of growths within such cavities as the mouth and vagina, it was desirable to pass the *x*-rays through a cylindrical glass speculum passed through the center of a screen of sheet tin. At first, an exposure of only five or ten minutes should be given, three times a week, but the time of exposure may be gradually increased to twenty minutes or more. The exposures should be especially brief in the case of actively growing tumors. The sound tissues are not affected by the exposures required for this method of treatment. Dr. Williams said that a microscopic diagnosis had been made for him in almost every one of his cases, which included epithelioma, rodent ulcer, carcinoma, papilloma of the larynx, spindle cell sarcoma and keratosis. He thought it probable that most external growths could be made to disappear by the *x*-rays, but in the more advanced, though operable, cases one would have to choose between the *x*-ray and operation. In the inoperable cases, or where the patient declined operation, the *x*-rays should certainly be used. It was worthy of note that a trial of two weeks would ordinarily be sufficient to show whether or not the *x*-rays would avail in a given case of epithelioma. Thus far, every external new growth that he had subjected to the *x*-ray had healed or was rapidly improving. He believed this treatment would prove beneficial in certain forms of cancer of the breast, and nodules recurring in the scar of operation were certainly amenable to this new agency. The absence of any dread of operation, the painlessness of the treatment and the excellent cosmetic effects secured would prove potent factors in bringing many patients under observation at a much earlier stage than heretofore. At the present time, however, the physician was not justified in promising a good result from the use of the *x*-ray in the deeply-seated growths, and it was his duty to warn his patients of the present narrow limits of this method of treatment.

DR. WILLIAM JAMES MORTON said that he had found no occasion to employ the aluminum screen, for, while it could not be denied that such a shield cut off the electrostatic field, it was not the electricity but the *x*-ray that caused the burns. Neither did he make any effort to insulate the lead plates, but instead made use of common tin foil, which he found exceedingly convenient for the purpose. He had found the medium soft and the hard vacuum tubes the best for this class of work and had learned to divide his cases into four classes, viz., 1, exterior or superficial; 2, interior growths situated beneath a healthy skin; 3, operable cases and, 4, inoperable cases. A rather soft tube should be used for the treatment of cases of the first class. As regards the operable cases, he did not feel at present like advising the use of the *x*-ray in preference to the knife, though he had found carcinoma of the breast, both initial and recurrent, yield well to the *x*-ray. Dr. Morton reported, among others, one case, proved by the microscope to be carcinoma of the breast, in which, after three operations, he had made use of the *x*-ray, and had apparently effected a cure. A patient was shown who was still undergoing treatment for a large osteosarcoma behind the ear. The young woman had received 20 treatments and only about one-tenth of the growth now remained.

DR. WILLIAM B. COLEY described his experience with this treatment. Several cases of sarcoma had shown no permanent improvement, but one case of lymphosarcoma and another recurrent small round-cell sarcoma of the neck had shown marvelous improvement. This was particularly true of the latter case, which was accompanied by a complete history dating back ten years.

DR. CHARLES W. ALLEN exhibited a case of lupus of twenty years' standing that had been apparently cured by the *x*-ray. He said that he had almost invariably noted cessation of pain after the first treatment.

DR. PERCY TURNER briefly narrated his experience at the Roosevelt Hospital, and showed two patients, one a case of epithelioma of the face, and the other an erythematous lupus

of the same region. He said that his results in carcinoma had been discouraging.

DR. GEORGE C. HOPKINS, Brooklyn, said that he, too, would dissent from the view entertained by the reader of the paper concerning the necessity for using the screen. He had treated a very large number of cases and had never produced an *x*-ray burn. Most of his work had been with recurrences in the line of operation scars, and here he had met with considerable success. He believed that if a static machine and a low vacuum tube were used there would be little danger of producing *x*-ray burns.

DR. H. G. PIFFARD thought many of the external growths that had been treated with the *x*-ray could have been treated just as successfully, and in a much shorter time, by curettage and the application of the galvano-cautery.

DR. WILLIAMS, in closing, said that as it was possible to produce a dermatitis even when a screen was used, and that it was also possible to produce a severe burn by the brush discharge, it seemed to him wiser to make use of a screen and so reduce to a minimum the risks of this method of treatment.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### Rectal Alimentation.

The technique of rectal alimentation must be properly carried out if the best results are obtained. The importance of a proper knowledge of the preparation of the food and the method of its introduction is evidenced by the number of diseases in which it must be used. Mention may be made of some of these conditions, such as ulcer and carcinoma of the stomach, persistent vomiting from any cause, and certain abdominal operations.

In cases of tubercular laryngitis the pain is so severe that the swallowing of food in any form is almost impossible; in diphtheria rectal feeding is sometimes necessary. In the treatment of appendicitis, where surgical measures are not carried out, complete rest of the intestinal tract is sometimes advised for a number of days, during which time the patient may be sufficiently nourished per rectum, thus lessening the peristalsis otherwise produced by food introduced per os.

It is important to bear in mind that the lower portion of the large intestine has not the power to digest, and consequently any alimentation thus introduced should be predigested or peptonized. Some authors state, among them Ewald, that milk will be properly assimilated when introduced per rectum. Others are in the habit also of giving raw beaten eggs and beef juice, but it is a question whether any of them are of great nutritive value when given without first undergoing the process of predigestion.

Dr. N. S. Davis, Jr., in the "System of Phys. Ther.," states that peptones are well absorbed. So also is the white of an egg when a little salt is mixed with it. Raw beef juice in his opinion is completely absorbed. Sugar is readily absorbed, but is especially liable to provoke diarrhea, for in concentrated solution it irritates the mucous membrane of the bowel. It will, however, be retained if introduced in a solution of not more than 20 per cent. strength. Starch, according to Davis, is perfectly absorbed, while fats are not absorbed. He gives no reason why the above substances are absorbed when they have not been predigested, except that the epithelial cells of the mucous membrane are probably capable of modifying them chemically. By reversed peristalsis, food introduced by the bowel may reach the small intestine unless there be some obstruction along the course of the canal.

Yeo holds a contrary opinion and states that only water, salts and peptonized foods can be absorbed. It should be remembered that the mere retention of the enema is no evidence that the patient is being nourished. Rectal alimentation, as

has been stated, may supply sufficient nourishment, when employed, for a limited length of time and should only be resorted to as a temporary means of tiding a patient over until his stomach is again able to properly retain and digest the food. The lower bowel should be properly prepared to receive the nutrition by first flushing it out with a high enema of plain water or of weak soap suds. Then the patient should rest about one hour before the food is introduced. The patient should be instructed to lie flat on the back with the hips slightly elevated or upon the left side. The nutrient enema should be given at about 100 F. The tube should consist of an ordinary flexible large catheter to which is attached a glass tube five or six inches in length, to which in turn is attached a funnel which should be held at an elevation of two or two and a half feet above the bed. The tube should be inserted at sufficient length into the bowel so that the upper end will have passed above the sigmoid flexure and the fluid allowed to run slowly into the bowel.

The amount to be introduced at each feeding should not exceed six or eight ounces (180 or 240 c.c.); larger amounts are liable to provoke increased peristalsis and cause evacuation of the contents. Irritation of the bowel must be avoided if possible by not feeding oftener than once in six hours; if necessary five to ten drops of tinctura opii may be added to each feeding to lessen the irritability of the mucous membrane.

Dujardin-Beaumont advises the following nutrient enema: One glass of milk to which is added the yolk of one egg beaten up; then add 2 dessertspoonfuls of solid peptones or 2 table-spoonfuls of liquid peptones, and 7 or 8 grains (one-half gram) of sodium bicarbonate.

Daremborg, as stated in the "Manual of Clinical Therapeutics," states that he kept alive a patient who was suffering from stricture of the esophagus, for fourteen months by means of a peptonized enema prepared in the following manner: Place in a glass vessel 7500 grains (475 grams) of finely minced meat as lean as possible; pour on this about 100 ounces (3000 grams) of pure water and an ounce (30 grams) of hydrochloric acid of a density of 1.15. To this add 40 grains (2.5 grams) of pure pepsin. Digest this mixture for 4 hours at a temperature of 112 F. Then let it boil, adding meanwhile a solution of sodium bicarbonate (17 grains to the ounce, or 1 to 30) until the mixture has a slight alkaline reaction; this will require 5 or 6 ounces (150 or 180 grams) of the solution. Strain the liquid and concentrate to 50 or 60 ounces (about one and three-quarters kilograms). Half this amount is given by the rectum daily.

Ewald's formula is as follows: Beat up two or three eggs with a tablespoonful of cold water; boil a teaspoonful of flour with a 20 per cent. solution of grape sugar and add a wine-glassful of red wine; stir the egg slowly into this mixture when it has cooled. The above mixture is an indication of his opinion that the absorption of nutrient enema may take place without peptonization.

Leube recommends the following as a nutrient enema: Take about 5 ounces (150 grams) of finely scraped meat; chop it still finer, add to it one and a half ounces (45 grams) of finely-chopped pancreas free from fat, then add about 3 ounces (90 grams) of luke warm water and stir to the consistence of thick pulp.

Ordinary peptonized milk is, for all practical purposes, the best food for rectal nourishment. It may be prepared as follows: To three parts of pure milk add one part of water. Pour one pint of this mixture into a jug after bringing it to a boil. When it has cooled down to about 140 F., one or two teaspoonfuls of liquor pancreatici and a little sodium bicarbonate should be added. Set aside for one hour and boil again for one or two minutes; cool to 100 F. and the enema is ready for use.

The following nutrient enema is sometimes used, prepared according to Scheffer's formula:

|                                   |      |     |
|-----------------------------------|------|-----|
| R. Infusi carnis (beef tea) ..... | 3iv  | 124 |
| Acidi hydrochlorici .....         | m. x | 60  |
| Pepsini glyceriti .....           | 3ii  | 750 |

M. Sig.: As a nutrient enema.

Bidwell gives the following formula:

|                        |     |     |
|------------------------|-----|-----|
| R. Milk .....          | 3ii | 62  |
| Beef tea .....         | 3ii | 62  |
| Yolk of egg .....      | i   |     |
| Sol. pancreatici ..... | 3i  | 375 |

M. Heat one hour before use at a temperature of 100. Sig.: Use as an injection once in six hours.

A very good combination may be prepared as follows:

|                           |      |     |
|---------------------------|------|-----|
| R. Beef peptonoids .....  | 3ii  | 750 |
| Yolk of egg .....         | i    |     |
| Spts. frumenti .....      | 3ss  | 16  |
| Tinct. opii .....         | m. v | 33  |
| Sodii chloridi q. s. .... |      |     |
| Peptonized milk .....     | 3vi  | 186 |

M. Sig.: Use as an enema once every six hours.

Leube also recommends the following formulae:

|                  |       |     |
|------------------|-------|-----|
| R. Peptone ..... | 3ii   | 62  |
| Milk .....       | 3viii | 248 |

Or:

|                      |         |     |
|----------------------|---------|-----|
| R. Three eggs        |         |     |
| Sodium chlorid ..... | gr. xlv | 3   |
| Milk .....           | 3viii   | 248 |

Or:

|                      |       |     |
|----------------------|-------|-----|
| R. Grape sugar ..... | 3ii   | 62  |
| Milk .....           | 3viii | 248 |

Or:

|                 |     |     |
|-----------------|-----|-----|
| R. Starch ..... | 3ii | 62  |
| Milk .....      | 3ix | 280 |

N. S. Davis, Jr., employs the following:

|                             |       |     |
|-----------------------------|-------|-----|
| R. The white of three eggs. |       |     |
| Starch .....                | 3ii   | 62  |
| Sodium chlorid .....        | 3i    | 375 |
| Water .....                 | 3viii | 248 |

Somatose, the predigested meat preparation, is an admirable product for rectal alimentation. There is also upon the market a great variety of peptone preparations of predigested meat in powder form, which may be used in the preparation of nutrient enema.

## Medicolegal.

**Telling Character of Injury Not Waiver of Privilege.**—The third appellate division of the Supreme Court of New York says, in the case of *Dunkle vs. McAllister*, that no court, it believes, has yet gone so far as to hold that it is a waiver of the right conferred by statute to enjoin secrecy in an attending physician, when all that can be said is that the patient himself became a witness and told the character of the injury he was suffering from. That appearing to be all that the patient did in this case, the court holds that there was no error in excluding, upon his objection, the opinions of certain physicians, formed from an examination of his wound while attending him as a patient, that it was not a gunshot wound, but the result of a blow.

**Statements of Injured Person to Physician.**—The Supreme Court of Ohio holds, in *Pennsylvania Company vs. Files*, a personal injury case brought by the latter party, that testimony of a physician, who had made an examination of the party before the trial, as to statements made by the party at that time, in regard to his suffering from the injury, was incompetent as evidence, the examination not having been made for the purpose of treating the party, but for the purpose of enabling the physician to testify as an expert at the trial. Such evidence, the court says, is to be distinguished from evidence of a like character, given by a physician called on for treatment. In such case, what the patient may say to his medical adviser as to his condition and how he suffers may be admitted. It is to be presumed in such case that he states the truth, as it is to his interest that he should do so, and not mislead the physician by false statements as to his condition. He is under a strong motive in such case to state the truth, and it

is on this ground that such evidence is admitted. But where the physician is called on, not for the purpose of treatment, but to enable him to give evidence in a pending or proposed suit, no such sanction of the truth of what he says exists. On the contrary, he is under a strong motive to deceive the physician, and, not being under oath, may, with impunity, make such statements as he sees fit. What he says to a physician under such circumstances is self-serving in character, and should not be admitted in evidence; and, for a stronger reason, like statements made to third persons, not physicians, under similar circumstances, are incompetent.

**Illinois Medical Practice Act and Osteopathy.**—The Supreme Court of Illinois says, in the case of *People, to Use of State Board of Health, vs. Gordon*, that it thinks it clear, from the several sections of the act of 1899 to regulate the practice of medicine in the state of Illinois, that the State Board of Health is authorized to divide those who desire to practice medicine in this state into two classes; that is, those who desire to practice medicine and surgery in all their branches, and those who desire to practice any other system or science of treating human ailments without the use of medicine or instruments. In this case, the party said that his treatment was a mental science. But he said, too, "I first make a diagnosis. Then I remove the cause for that condition by working and freeing the nerve force. . . . I get as near the muscles as I can. If a person is fleshy, it takes more force." He also flexed, or, as one witness said, bent the limbs. The court declares that it is at a loss to perceive how it could be said that his own testimony did not tend to show that he did treat and operate on patients for physical ailments, within the meaning of section 7 of the act, which defines who shall be regarded as practicing physicians, within the meaning of the act, as including both classes above mentioned, and defines the practice of medicine as including all "who shall treat or profess to treat, operate on or prescribe for any physical ailment or any physical injury to or deformity of another." In short, the court thinks that all the testimony tended to show that he practiced what is known as osteopathy, at least, the treatment was of that nature. It says further that it hardly thinks that the large school of osteopaths and those who believe in their method and system of treatment, would be willing to concede that such treatment is no more than that which a trained nurse might administer. While it may be truthfully said that it is not the practice of medicine in the common acceptance of that term, it can not be claimed that it does not "profess to treat, operate on or prescribe for any physical ailment or any physical injury to or deformity of another," and certainly it can not be insisted that such persons do not practice another "system or science of treating human ailments without the use of medicine internally or externally." Nor is the court able to see how, under his own evidence, the position advanced could be maintained that he was exempt from the operation of the statute by the last clause of the proviso to section 7; that is, that he was a person "who ministers to or treats the sick or suffering by mental or spiritual means, without the use of any drug or material remedy." Very clearly this provision, the court says, means that those who pretend to relieve the ailments of others by mental or spiritual means shall not be considered within the act; but if this party, under the proof in this case, could bring himself within that exception, then every one who treats diseases without administering medicine, either externally or internally, could also be brought within the exception. Few, perhaps, if any, physicians attempt to treat the sick and suffering without appealing to the mental faculties, to a greater or less degree, in aid of the remedies they apply or prescribe; but that is not treating the sick by mental or spiritual means. Again, the court says, that merely giving massage treatment or bathing a patient is very different from advertising one's business or calling to be that of a doctor or physician, and, as such, administering osteopathic treatment. The one properly falls within the profession of a trained nurse, while the other does not.

**Authority Required for Appointment of Health Officer.**—The Court of Civil Appeals of Texas says, in the case of

*Brumby vs. Boyd*, that the right on authority is select and appoint public officers is one of the highest prerogatives of sovereignty, and the delegation of such authority by the sovereign power must be clearly shown by the person claiming the right to exercise the same. The power to appoint officers—excepting, perhaps, those who are to assist him in the discharge of his personal executive duties—is not inherent in the chief executive, but must exist, if it exist at all, by virtue of the authority conferred upon him by the sovereign power. Consequently, for example, unless the sovereign power, the people, have, through the act of their legislature granting a charter to a city, conferred upon the mayor thereof the power to appoint a health officer to temporarily fill a vacancy in that office, caused by the death of the incumbent, the mayor has no such power, and any appointment made by him is absolutely void. A provision in a city charter that "in case of a vacancy in any elective office, from whatever reason, the council, upon nomination by the mayor, shall fill the vacancy by the election of some person by a vote of a majority of the aldermen elected and qualified," does not authorize the executive to make a temporary appointment of a health officer in the recess of the confirming or concurring body. Neither can act in the matter independent of the other, and no legal appointment, temporary or otherwise, can be made unless concurred in by both the mayor and a majority of the board of aldermen. But it was urged that upon the failure of the mayor and board of aldermen to agree upon a suitable person the right of the mayor to make a temporary appointment would arise from public policy, which requires that a vacancy in a public office should be filled. It is true, the court replies, that the law does not favor a hiatus in office, and the welfare of the citizens demands that a vacancy in the office of health officer of a city should be filled; but the city council of the city, to whom alone the authority to fill such vacancy was delegated, having failed to perform that duty, and there being, as before shown, no inherent power in the mayor to make such appointment, the office must remain vacant until filled in the manner prescribed by the law. Nor does the court consider that the council could legally authorize one of the health inspectors of the city to perform the duties of health officer pending the filling of the vacancy in the office in the manner required by the charter; besides, both offices being offices of emolument, to allow one person to hold them in even that manner would be in violation of the state constitution. Then, either an appointment by the mayor or by the council, being not merely irregular and informal, but absolutely void, neither's appointee would have any colorable right to the office, nor could be regarded as the de facto health officer of the city.

1. **Surgery and Obstetrics.**—Cragin calls attention to the importance of surgical training for obstetricians, especially in the technique of asepsis, which is of importance in obstetric work and which a surgical training can best give. The obstetrician needs special training in preparation for the meeting of hemorrhage and treatment of lacerations, obstruction deliveries, eclampsia and infections.

3. **Gangrenous Appendicitis Without Symptoms.**—The case reported by Evans was that of a child 9 years old. In the five days' sickness there was a steady advance in the pulse and toxemia. The temperature remained practically normal until the fourth day. At no time were there any cardinal symptoms of appendicitis or peritonitis. The autopsy showed that the appendix was straight, of large lumen, unobstructed by any foreign body, without adhesions or malformation. There was

a bacterial infection of the peritoneum without perforation of the walls of the intestine or appendix and gangrene in that part of the lumen touching the appendix. The patient died before the peritoneal symptoms had developed. This case shows that an infection can exist in the appendix which will end fatally, not only before peritoneal symptoms exist, but before giving any indications of its source. If, in the presence of constitutional symptoms of toxemia of unknown origin, there exists the slightest suspicion of abdominal involvement, Evans suggests an exploratory incision for the purpose of diagnosis and further interference if necessary.

4. **Strabismus.**—Derby insists on the importance of long continued daily exercise and the training of an amblyopic eye. A closely fitting screen over the well eye is necessary, and for half an hour at a time daily and sometimes twice a day the deviating eye is to be exercised by writing and reading. He thinks that this is of great importance and we ought to see that the advantage of good binocular vision is secured.

5. **Internal Hemorrhoids.**—Bullard discusses four methods of treatment of hemorrhoids, the injection method, the Whitehead operation, the ligature and the cautery. The first two he thinks should be abandoned. The only value the injection method has is its applicability in cases of dangerously ill patients, to whom an anesthetic can not be administered. But the risk is so great that it is better for the time to adopt palliative measures. The Whitehead method has no advantages. The ligature and clamp and cautery operations are the proper procedures to employ, the latter possessing the advantages of a more speedy and painless cure and of being less liable to complications.

7. **Obesity.**—Studying the polysarcia of adolescence, Stern finds in some cases it diminishes toward the close of the second or beginning of the third decade of life, while in others it continues to exist after maturity and he thinks that this seems to be of some etiologic importance. Where it persists after the completion of growth, the underlying causes are undoubtedly the same as those existing in the adult, but where it disappears in maturity it must be something else. The cases abiding after individual development he classifies as metabolic, and those which subside with the approach of adult life as transitory. Both forms occur in both sexes, but he has found the metabolic factor more frequent among boys, while the specific form certainly predominates among girls. The metabolic obesity of adolescence is virtually nothing but a juvenile modification of that which he has described as metabolic obesity in the adult, understanding by that a condition in which obesity concurs with a normal or slightly subnormal degree of body-density. It is the most common of all the types and is always due to the excessive ingestion of nutriment or to insufficient oxidation in the organism or to both together. He gives the proportion of calories required normally in conditions of rest and the excess in these cases which tends to produce this abnormal growth. In some exceptional instances metabolic obesity during infancy and adolescence may be due to infantile predisposition, but in the majority of cases it is instead due to the habit of living adopted by parents and children, that is, either the same degree of superalimentation or the lack of body-activity or the combination of the two. In adolescence the metabolic obesity is not indicative of any important specific organic changes. The transitory obesity of adolescence occurs only in youth and Stern thinks there is little doubt that it is caused by certain metamorphic anomalies which are incidental to pubescence and disappear before or at the completion of systemic development. Some anomalies are also apt to occur at the climacteric age in women and after orchidectomy and oophorectomy in consequence of the pronounced alteration in the organism. The greater frequency of this form among girls is explained by the fact that the changes occurring at puberty are more decisive in the female than in the male. Superalimentation is not a causative factor of specific obesity and this must be due to diminished intra-organic oxidation and he attributes it to the perverted function of the thyroids, parathyroids or both. The reasons for this are first, the disappearance of the thymus gland and the marked development

of the thyroids at puberty. The more frequent occurrence of thyroid affections in girls than in boys and our physiologic and clinical experience as regards increase in protoplasm oxidation after administration of thyroid gland or its preparations. He notices certain peculiarities of the type in the specific form. The disposition of fat is more frequently on the breast and extremities, while in the metabolic variety it occurs in and upon the abdomen, region of the hips, etc. In the specific form of the affection the hair of the head is full and attains great length, while it is much less abundant and apparently short in the metabolic obesity. Neither form of juvenile obesity demands treatment when the weight is not excessive, so as to interfere with the function of certain organs, or grave concomitant disorders exist. Uncomplicated cases of less than 30 per cent. overweight should not be subjected to any continuous treatment. If, however, metabolic obesity has already appeared at an early age in other members of the family, proper dietetic treatment may be of value, but it will be of no avail in checking transitory obesity which is the result of developmental anomalies. In all cases our therapeutic efforts should be directed rather to complications and concomitant disorders than to the obese condition itself. But if the condition is extreme and giving cause for alarm the thyroid preparations may be employed. A safe form of administering thyroid substance, a tablet which he has made use of for a number of years, is as follows:

|                                      |     |
|--------------------------------------|-----|
| R. Arsenous acid.....gr. 1/60        | 001 |
| Adonidin .....gr. 1/12               | 005 |
| Thyroid gland, dry powder .....gr. 2 | 12  |
| M. Ft. C. T. No. i.                  |     |

Physical treatment, in any of its branches, may be of benefit in individual cases of transitory obesity.

9. **Hydrocele.**—Coley and Satterwhite report a number of cases treated by the injection of pure carbolic acid by the Levis method or a modification of it. They are convinced that the carbolic injection is by far the best method. It is easily performed and almost uniformly successful, the only disadvantage being the doubt as to its always being free from risk. While this may not be great, a few serious results have occurred, sufficient to deter many patients from having it tried. Although this is valuable and effective in the great majority of cases, there are a few in which the open treatment of resection must be employed and here the method of von Bergmann of resection of the superficial tunica vaginalis seems the best and most certain and should never require more than eight or ten minutes in its performance.

11. **Hippus.**—Newton reports a case and notices the literature. He has found but one case closely corresponding to his own and that was one by Oestreicher mentioned in Knies's work of "The Eye in General Diseases." The value of the symptom, he concludes, is but poorly determined. New researches and new study are required to determine it.

12.—See abstract in THE JOURNAL of March 1, p. 604.

13. **Sand Filtration.**—The value of sand filtration is pointed out by Anders, who illustrates it by experience of various places, including Hamburg. While its primary cost is greater, and while it requires more space it has an undoubted superiority to mechanical filtration, which is 2 more expensive to operate and demands the utmost care in the artificial chemical processes which constitute the system.

14. **Bacillus Coli.**—Moore and Wright have investigated the bacillus coli as to its occurrence in other species than man. They have examined 44 animals, including horses, cattle, sheep, pigs, dogs and chickens. The action of the colon bacilli on the sugars and milk shows that these fall naturally into two groups, viz., those that ferment the three sugars with the formation of gas and those that ferment dextrose and lactose only, corresponding with the two varieties described by Smith. The quantity of gas produced and the relative quantities of H and CO<sub>2</sub> varied somewhat in the different cultures, but not sufficiently to justify the naming of special varieties or groups. In frogs the results were negative so far as the colon bacilli were concerned, but in rabbits it seemed to be present in about 1 in 4. In all the cases the cultures fermented the three sugars

and produced gas. The variation in the pathogenicity of the cultures from the different species of animals is very marked. Guinea-pigs inoculated with cultures from dogs respond quickly, but apparently not with those from other animals. Additional results will be necessary before conclusions can be deduced.

15.—See abstract in THE JOURNAL of February 8, p. 413.

17. **Movable Kidney.**—Sometimes the pain complained of in movable kidney continues after operation and four cases are reported by Mallett, who accounts for it by assuming that in most instances the kidney has been fixed in a malposition and that it is attached in a position externally rotated on its vertical axis, interfering with the function of the ureter and vessels. As far as he knows, this point has never been emphasized and he calls the attention of surgeons to exercising care in the performance of nephrorrhaphy, and to see that the circulation of the ureters and vessels is not interfered with.

18. **Blood Examinations.**—Willson's article is a reply to the recent condemnation of blood tests by Deaver and Baldy, who have minimized the importance of blood examinations in surgery.

19. **Paresis.**—Pickett notes the fact that paresis without delusion is a very common type; the old type of delusion of grandeur is much less frequent than seems to be popularly believed. He mentions among the diseases liable to be confused with this disorder, so-called organic dementias, chiefly those due to hemorrhage, thrombosis, etc., dementia precox, epilepsy and alcoholic insanity. His statistics cover cases up to 65 years of age, which fact should be noted. The crucial tests of true paresis are, first and most important, the state of the pupils. He tabulates the types of the pupil changes observed. The consensual reflex, upon which Pickett lays much stress, was seen in a comparatively small percentage, but the Argyll-Robertson type, that is, marked impairment of light reflexes, occurs in over 50 per cent. The knee-jerk, he says, when abnormal, accompanying any psychosis of neurosis in middle life, suggests paresis. It was absent in 31 per cent. of the cases, diminished in 10 per cent., and only normal in 10 per cent. Paralytic attacks and convulsions are also noticed as well as hypochondriac delusions and remissions. He lays much stress on hereditary degeneracy, giving family histories in 89 cases, in 75 per cent. of which vicious constitutional conditions existed in the heredity. He includes under this head: consumption, cancer, heart disease, asthma, nephritis, etc. The purely neurotic histories would not come to so high a percentage. He says in conclusion that it is profitable to suggest two lessons from our study of paresis. First, for our patient: That immunity from paresis rests not on freedom from the great infection alone, but, as the older writers believed, on abstinence from all excesses. Second, for ourselves: That diagnosis, the principal thing required of us in the present state of our knowledge of paresis, depends so much upon a practical acquaintance with the "paretic manner," that no amount of fine training in the best schools can take its place. Impressed with this fact by daily contact during several years, with some scores of the best graduates of our Philadelphia medical colleges, he would urge the importance of teaching in the asylums. An hour in the wards is of more value than many lectures.

21. **Nitrous Oxid and Ether Anesthesia.**—Le Breton's experiences with this form of anesthesia are given in a general way in this article. He quotes other authorities also in favor of this method. It is the writer's custom to remove the inhaler about once every two minutes to allow the patient one or two inspirations of air during the ether anesthesia and thus avoid asphyxiation. Unless too much ether is required in this method there are few unpleasant after-effects. The changes of technique which he has adopted with the use of the Goldan apparatus since the appearance of his first article are as follows: "The rubber mouth-piece may be kept sterile by placing it in a weak formalin solution after each operation. The quantity of ether inhaled may be determined by using as a holder a graduated nursing bottle with a cork perforated by two metal tubes, such as ordinarily is used to drop chloroform upon a chloroform inhaler. Dr. Mann originated a little scheme for introducing the ether which the writer has found of great

service. By boring a small hole in the metal cylinder which holds the gauze, and inserting into it the end of one of the tubes in the cork of the nursing bottle, the ether is allowed to trickle upon the gauze quietly and rapidly. About twenty seconds after starting the gas the first dose of ether may be run in, and at the end of the second minute, by which time the gas has made the patient unconscious, the gauze in the cylinder has been well saturated with ether. At the end of the fourth or fifth minute a return to semiconsciousness is sometimes noted, but continued small doses of ether quickly control the situation."

**22. Supra-Orbital Reflex.**—In September, 1901, McCarthy published his first description of what he considered a pure sensory motor reflex, to which he gave the name of supra-orbital reflex. Since that publication the symptoms have been discussed by Hudovernig, who considers it an overflow of contraction from the occipito-frontalis to the orbicularis, and by von Bechterew, who considers it only partially a true reflex and to a certain extent the transmission of mechanical impulses along the different fascia and muscular fibers. In order to exclude the mechanical errors he tried irritation of the skin areas by means of heat, cold and pain, and accurately outlined the supra-orbital distribution so that he is sure that the name supra-orbital reflex is justified and his original explanation a correct one. A careful study of the reflexes in the upper portion of the face, which is richly supplied with sensory nerve filaments of the fifth nerve, all of which are accessible to mechanical or sensory irritation, shows that there are several independent and distinct reflexes there occurring as follows: "1. A pure sensory-motor reflex, in the nature of a skin-muscle reflex, elicited from the supra-orbital distribution exclusively. 2. A periosteal reflex may be obtained when there is an excited condition of the reflexes, by irritation (percussion) over the malar arch or the periosteum of the nose (v. Bechterew, Overend). 3. The corneal and conjunctival reflexes, by irritation of these structures. 4. The corneo-mandibular reflex of v. Solder, a lateral movement of the lower jaw produced by irritation of the cornea." (*Neurologisches Centralblatt*, 1902.)

**25. Serumtherapy.**—The progress of investigation in the direction of serumtherapy of typhoid is reviewed by Ewing, who says that the problem of the serumtherapy of the disease is the preparation of a serum which is principally bactericidal and not antitoxic as in typhoid. It remains for investigators who have the experience and means to combine the results that have been made and to determine what success can be secured in the treatment of typhoid fever by the injection of serum and visceral extracts from animals which have been treated with a view of producing culture immunizing bodies. He thinks the outlook is fairly hopeful, if not in the production of a curative serum, at least as regards progress in our knowledge of artificial immunization both in this disease and other obstinate affections.

**27. Typhoid Bacilli in the Feces.**—Higley has studied the occurrence of typhoid bacilli in the feces and gives a résumé of the cases with the following conclusions: 1. During the second week of typhoid fever, when technical aids are of the greatest value to the practitioner, isolation of typhoid bacilli from the feces gives slightly better results than does the Widal test. These two methods used in combination, when the tests are carefully and persistently made, render material aid in the diagnosis of this disease previous to the appearance of distinctive clinical symptoms. 2. By the use of the Hiss isolation method, especially with the substitution of the new plating medium, the detection and isolation of typhoid bacilli are, to one familiar with bacteriologic methods, simple, reliable and practical.

**28. Widal Reaction.**—Libman made 3514 tests in 860 cases. He finds the positive Widal reaction always means the presence or previous existence of typhoid. A partial reaction should be absolutely ignored. The negative reaction does not exclude the existence of typhoid fever. It occurs under any of the following conditions: 1, the reaction has already disappeared; 2, the reaction may only appear later; 3, the culture may be at fault; 4, the case is clinically one of typhoid and

there may never be a positive reaction; 5, the disease is not typhoid. A negative reaction may occur if the patient is suffering from paracolon infection, and still, for the practitioner, the case is clinically identical with typhoid. Scientifically, the Widal reaction is of the greatest value in establishing the presence of infection by the typhoid organism where the clinical typhoid fever does not exist. It is practically also of use, but not so valuable as we wish in many cases. In many cases it alone can establish the diagnosis. This is practically true of atypical cases in which pneumonia or meningeal symptoms usher in the disease, which are more common in children than in adults. He thinks that it is advisable to test the blood early in any fever case, the diagnosis of which is not known. If the result is negative, as is apt to be the case, the later positive reaction stamps the case as typhoid and it can not be attributed to an earlier attack of the disease. If a case present the classical symptoms of typhoid fever, it is not necessary to examine the blood, except possibly for two reasons: 1. If later in the course of the disease some perplexing symptom-complex arise, one can be sure that the original diagnosis was correct. 2. If some unusual observation is made, the case can be utilized for the purpose of advancing our knowledge of typhoid fever. If the case be a doubtful one, the reaction should be made every two days until it becomes positive, or until in other ways a positive diagnosis of the condition has been established by the practitioner.

**30. Adrenal Substance in Typhoid Hemorrhage.**—Coleman maintains that we are justified in advocating the free administration of adrenal substance in cases where the ordinary reaction hemostatics are not sufficient. It can do no harm and may be of the greatest value.

**32. Suture of the Arteries.**—The various methods that have been devised for suturing the arteries are detailed by Hubbard, who gives a résumé of twenty operations from the literature. He tried to show by experimentation that transplantation or anastomosis of arteries was possible and three experiments on dogs are reported, which seem to indicate this possibility, though the results are imperfect. If this were possible, he has an idea that in a certain number of conditions, such as some abdominal aneurysms for example, this procedure will be of some value. All the dogs survived the operation and were killed within two weeks and the conditions observed. In the first case an incision into the artery was sewed up. The recovery was good. In the second case there was a resection of the left carotid and a lateral anastomosis of the ends. At death there was found to be soft blood clot occluding the artery at the point of union, though air passed freely. On the same dog a similar operation was made on apparently the other carotid, only cutting out a portion of the wall to make the circulation freer, though it is stated as the same one. Anastomosis seemed to be free, though there was a clot in a hole where a stitch had given way, causing secondary hemorrhage at the time of death.

**33. Catgut Ligatures.**—From his experimentation Cabot concludes: 1, that in rabbits chromicized catgut of No. 1 size is retained longer than is desirable in a suture material for surgical use; 2, that plain catgut of No. 1 size is retained a sufficient length of time; that is to say, a minimum of three weeks; 3, that catgut prepared by dry heat is more rapidly absorbed than that prepared by moist methods; 4, that the time required for absorption increases very rapidly with the increase of size, as No. 2 gut took from two to three times as long to absorb as No. 1. The application of these results to operative surgery is taken up, and he emphasizes the following points which seem to him important. 1. In order to get the best results from catgut, care must be taken to select the size and preparation best suited for each occasion. 2. The use of too large sizes is one cause of unsatisfactory results. 3. Care in tying and cutting catgut ligatures is essential to safety.

**34. Catheter Sterilization.**—From the results of his tests, Cotton claims that all the gum-elastic catheters and bougies ordinarily sold may be boiled repeatedly and for long periods in saturated (or something less than saturated) solutions of ammoniac sulphate or sodic chlorid without essential damage.

New instruments show no damage whatever, used instruments only a deterioration that is of no great consequence. As to a choice between the two, he feels a little surer of the ammoniac sulphate, perhaps, but would choose it not so much because of this as because it is easier to handle and spatters less when it boils down than does the common salt. As to the weaker solutions of common salt, they seem to be all right, but the tests made are too few as yet to be conclusive. At all events, the use of these more dilute solutions has no obvious advantage and has the disadvantage of lowering the boiling point. The methods have not been tested bacteriologically because it seemed superfluous.

**35. Uterine Retrodisplacements.**—Coggeshall's article is a demonstration of Goldspohn and Gilliam's operations, which he thinks are much superior to any method of shortening the round ligaments by doubling the proximal portion upon itself within the abdominal cavity.

**36. School Hygiene.**—Wright notices the various conditions bearing on the health of school children. First, the site of the school house, which should be a healthy one, and the number of pupils occupying a room, which should not be over 40 or 50, allowing about 20 sq. ft. of space for each. He favors natural ventilation rather than an artificial method. A northern light is preferable to any other and should be introduced from the left side of the pupil. The desks should be properly adjusted to the pupils, for this has much to do with the production of spinal curvature and sight defects. He thinks one of the most important factors in the causation of disturbances of the nervous and digestive system in the school children are due to the long school hours, and many failures of health and scholarship are due to them. A session of three hours, with a short intermission, is as long as any growing person should work. High school hours are generally bad, requiring an early breakfast and late dinner. The various diseases that should be watched for are enumerated, including tonsillitis and all digestive disturbances. Vaccination should be compulsory. A person who has been sick with scarlet fever should be kept from school at least until the process of desquamation has been completed, and even then he should not return until a thorough disinfection has been made of the person and premises. The danger of diphtheria is not over when the membrane disappears. Outbreaks of disease often have their origin in persons who have been allowed to return to school before they were entirely free from the infection. Measles and whooping cough are often slighted by teachers and parents, but they are really serious disorders. Pupils should have nothing in common, such as pencils, drinking cups or books. Medical inspection, if properly performed, seems to offer the best chances for lessening sickness. It should include: 1, sanitation of the buildings, inspection of the heating and ventilating apparatus, general cleanliness, water supply, closets, and the possible supervision of books, pencils, etc.; 2, examination of the pupils, which should be daily, for the prevention of contagious diseases and at stated intervals for the detection of parasitic diseases and vermin, and at least every term to ascertain if all pupils have been successfully vaccinated; examination several times a year of the eyes and ears in order to correct errors of refraction and defects in hearing. Many children naturally bright are considered dull simply because no one has discovered these defects. What might be called outside inspection is looking into the causes of absence of children and the nature of their illness. The custom of sending pupils from the school for this purpose is wrong and sometimes contagion is conveyed in that way.

**37. Visual Center Lesions.**—The case reported by Stricker occurred in a laboring man 60 years of age, who suffered severely from dizziness, vertigo and reeling gait followed by coma and later had very serious defects of vision. The vision fields were carefully examined and sketched. The consensual reaction of his pupils was perfect. There was no paralysis of the sphincter of the pupil, or of accommodation or other ocular muscles. He showed no form of other sensory or motor paralysis, nor did he disclose any form of psychic involvement. By exclusion, the author comes to believe that there is a localized cortical lesion restricted to the visual center in the region

of the calcarine fissure. The color sense was perfect in the retained portions of the field.

40.—This article has appeared elsewhere. See THE JOURNAL, XXXVII, §20, p. 1702.

**45. Chorio-Epithelioma Malignum.**—This condition, known as "deciduoma malignum," "sarcoma deciduo-cellulare," "sarcoma chorio-cellulare," etc., is described and its theories elaborately discussed by Pierce, who suggests the name given by Marchand as the most correct one. Its pathology is not altogether clear, but he considers it probably connected with some diseased condition of the endometrium. Why it usually follows abortion or normal labor is more difficult of explanation than why it should follow a mole, in which there is perhaps a higher degree and greater persistency of chorio-epithelial proliferation. He describes the symptoms and the treatment, which is essentially surgical, consisting practically in total extirpation of the uterus as soon as the diagnosis is made.

**46. Retroversion and Retroflexion.**—Davis concludes that our present knowledge favors Schroeder's conclusion that uterine retroflexion or retroversion uncomplicated by tubal or ovarian disease does not affect the health nor does it demand treatment. In the cases reported, the patients were greatly benefited by tonics and rest. The corset should be discarded and the clothing adjusted in each case so that there is no interference with the mobility of the viscera. When dragging or heaviness is felt in the pelvis the assumption of the knee-chest posture will usually bring relief. If the patient has been accustomed to wear a support and believes it necessary, that one which exerts less pressure will be found most successful.

**48. Perineal Laceration.**—The principles of operation for laceration of the perineum consist, according to Kreutzmann, in the adjustment of the layers so that each tissue is united to its corresponding part. He divides the operation into four different acts, which he describes thus: 1, dividing the vagina, cutting down into the septum between vagina and bladder or between vagina and rectum; 2, the detachment of the prolapsed diverticulum of the bladder from the vagina, if necessary from the uterus, or separation of the rectum from the vagina; 3, the careful apposition of the fascial tissue and of the muscles that belong to each other, by direct, exact, buried suture; 4, to finish the operation, the vaginal flaps may be resected and united, or they may be united without any resection, as the individual operator sees fit in every single case. No matter what the operation, the principle of procedure is always the same and he applies these principles to other operations such as vaginal fixation.

**49. Perineal Laceration.**—Boyce describes his method, the principal points of which are: "1, the use of buried and absorbable material for the principal sutures; 2, placing the deep ones in such manner that no skin suturing is required; 3, placing them so that the tension of the levator ani and its auxiliaries is restored; 4, avoidance, to a high degree, of infection from the rectum; 5, the facility of the operation; 6, emptying the bowels every day after operation."

**52. The Menopause.**—Cock's article maintains that the climacteric is a normal phase in woman's life and there should be no necessary symptoms whatever. The manifestations experienced are pathologic, not normal.

**55. Gonococcal Peritonitis.**—Frank and Koehler report several cases and say in conclusion that "to-day we are in possession of absolute facts pointing to the extensive activity of the gonococcus in regions formerly considered immune to its infection. The lesions produced may be summed up briefly as follows: endometritis, metritis, salpingitis, oöphoritis, peritonitis (both circumscribed and diffuse), proctitis, seminal vesiculitis, cystitis, carditis, pleuritis, parotitis, periostitis, osteomyelitis, bursitis, arthritis, tendo-vaginitis, muscular and subcutaneous abscesses, myelitis and meningitis. Metchnikoff's investigation of the nervous tissue, according to Nissl's method, has disclosed the fact that the toxin of the gonococcus has an undoubted deleterious effect upon the cord. Clinically, this is shown by the occurrence of neuralgias (ischias). Also probably due to the circulating toxin alone are the cutaneous lesions

at times observed. They are multiform in kind, erythematous, papular, urticarial, hemorrhagic, bullous and hyperkeratoid. Wassermann's investigations show that the toxin of the gonococcus has marked phlogistic powers and is bound during life to the bodies of the cocci. After their death its liberation may produce an active suppuration, the bacteria themselves disappearing by disintegration. This may explain the inability at times to find the organisms, though we may be firm in the belief that the condition or death may have been caused by their action."

56.—See abstract in *THE JOURNAL*, xxxvii, p. 1411.

**62. Reflexes from a Sympathetic Ganglion.**—Budgett and Snodgrass report experiments on cats to test whether a sympathetic ganglion can act as a reflex center. They severed the vagus above the trunk ganglion and united its peripheral end to the central end of the cervical sympathetic severed just below the superior cervical ganglion. The experimenters say: "As a result of these experiments, it seems highly probable that sympathetic neurons may respond to nerve-impulses transmitted to them by afferent nerve-fibers, but the possibility remains that the effects produced may have been due to an axon-reflex caused by the stimulation of efferent pneumogastric fibers."

**63. Syphilis.**—Hardaway deprecates the routine practice of continuous specific medication, especially in late syphilis. The need of building up instead of depressing the general vitality is emphasized. Tonics are indicated with or before the iodids and mercury. He says: "Perhaps twenty-eight years ago I became acquainted with the following formula for giving iodid of potassium—a method, I think, originated by the elder Bulkley, and which I have modified a trifle:

|                                       |      |      |
|---------------------------------------|------|------|
| R. Potassii iodidi .....              | 3ss  | 15   |
| Ferri et ammonii citratis.....        | 3i   | 3 75 |
| Tr. nucis vomicæ.....                 | 3ii  | 7 50 |
| Aquæ .....                            | 3iss | 45   |
| Tincturæ cinchonæ comp. q. s. ad..... | 3iv  | 120  |

M. Sig.: Teaspoonful in one-fourth glass of water after meals.

"The elixir of calisaya may be used instead of cinchona. This is a nasty mixture at best and is both chemically and pharmaceutically objectionable, but its virtues far outstrip its faults. With the majority of people the beneficial effects of this ideal tonic mixture are rapidly apparent, the appetite increases, the anemia disappears and a general feeling of well-being is engendered. Before breakfast and at bedtime a pill of opium and protoiodid of mercury is ordered. The dose of the protoiodid is usually one-fourth to one-half a grain and of opium about one-fourth grain. I regard opium as a drug of the very highest value in the treatment of ulcerations of all sorts, and I am convinced that in syphilis we get along better and quicker with it than without it. If for any reason it is desired to increase the dose of iodid, which, however, is rarely required, the patient may be given a saturated solution, of which he may add the necessary number of drops to the tonic mixture. Many years of constant employment of this plan of treatment has taught me its great value in suitable cases, and especially in the class of luetic lesions mentioned above; although, of course, I am fully aware that no one method can be infallible and that the physician must have many strings to his bow if he hopes to treat successfully so protean a malady as syphilis."

**64. Malarial Dermatoses.**—Eighteen cases of skin affections, urticarial, herpetic, etc., are reported and discussed by Engman. He remarks on the neglect these have received and offers the following as his conclusions: "1. It is highly probable that certain affections of the skin, as pruritus, urticaria, angio-neurotic edema, erythema multiforme, pompholyx, zoster, eczematoid eruptions and gangrene may be due to malarial poisoning. 2. In such cases there is generally a periodicity in the intensity of the eruption symptoms. 3. There may be marked or slight constitutional disturbances, or the eruption may occur without any other symptom of paludism. 4. Nephritis may complicate the picture in severe cases and seem to be the apparent cause of the dermal manifestations, whereas

the malarial infection is the sole etiologic factor. 5. When an eruption is associated with malarial infection it quickly recovers under the specific treatment."

76.—See abstract in *THE JOURNAL*, xxxvii, p. 933.

**77. Epiplopexy.**—Torrance reports a case and analyzes cases reported in the literature. He reviews the opinions of authors and calls attention to the fact that of the 10 cases that have been cured by this operation, in 7 the omentum was simply sutured to the abdominal wall and the surface of the spleen and liver left unirritated. He is convinced that this is the best operation. Oozing from these irritated surfaces makes an excellent culture medium for any germs that may accidentally get into the abdomen. Moreover, the operation was designed to relieve the strain on the liver cells and we should attempt to divert as much current from the liver as possible; therefore, we should not attempt to form any adhesions between the liver and abdominal wall. If he has an opportunity to do the operation again he will tap his patient on the day of the operation and make a small incision under local anesthesia, simply suturing the omentum without exploring the abdomen.

**78. Splanchnoptosis.**—A case of Glenard's disease is reported by Ingalls, who emphasizes the fact that surgery alone offers material aid for this class of sufferers, that is, to those in whom the symptoms are relieved by support, and they should have the benefit of an operation as soon as the condition is known. The work should be complete in every detail. He recapitulates the steps as follows: "1, suture of liver and kidney; 2, shortening of gastrohepatic omentum; 3, fixation of transverse colon; 4, general reconstruction of the abdominal wall."

**79. Rupture of the Intestine.**—Four cases are reported of rupture of the intestine by abdominal contusion; in all a small striking surface combined with great velocity characterized the accident. The only chance for these cases, he holds, is operation at the earliest possible moment. The danger of delay and the hopelessness of last-resort surgery are evident. It is necessary to note carefully the presence or absence of severe primary shock, and when it is present to take immediate measures to counteract it as far as possible. Large enemas of salt solution may favor fecal extravasation, but intravenous or subcutaneous infusions should be prompt and freely given. As soon as reaction is established, an incision should be made over the point of the blow whenever it is possible to locate it by the appearance of local pain or tenderness, and should be sufficiently free to permit of thorough exposure and inspection of the underlying intestinal coils. The injury is likely to be at once apparent and the injured bowel should be withdrawn from the cavity, and any possible contaminating matter that may have escaped wiped away. Mesenteric hemorrhage should be prevented and the intestinal wound closed and the intestinal tract examined, and finally the peritoneal cavity should be washed out with salt solution and close the incision. Resection may be required, but he would avoid it if possible. He does not think that simple peritoneal drainage is necessary or useful after the rupture has been tightly and carefully closed; but when one can not be satisfied as to this, it should be walled off from the rest of the cavity and left accessible to future inspection. In the majority of cases, however, this will hardly be necessary.

**81. Remote Results of Gall-Bladder Inflammation.**—Niles reports several cases of late symptoms produced by gall-bladder inflammation and says: "These and other experiences and observations in the same line lead me to conclude: 1. In this region inflammatory lesions often occur and produce permanent organic changes without giving rise to those characteristic signs and symptoms described in our text-books. 2. The anatomic relations and physiologic functions of the surrounding organs and tissues are such that peritoneal adhesions here may produce grave secondary lesions and symptoms that in the past we all have failed to recognize, or at least to correctly interpret. 3. In these obscure cases we are often compelled to resort to an exploratory incision to determine the exact condition and to rely exclusively upon surgical measures to remove or correct

the pathology. 4. In the light of our present knowledge, no experienced surgeon is justified in hastily declaring these cases to be hopeless or in permitting them to be deluded by a foolish faith in drugs or other unreasonable measures; it is his duty to offer them such chances as modern surgery affords so far as his ability and the conditions permit. Guided by my recent studies and personal experience, I shall in the future be, if possible, more thorough and radical in separating all adhesions and in taking every precaution to prevent their reforming."

**83. Weak Ankies.**—Wilson's conclusions are as follows: "The natural human foot best performs its functions when it has been freest from restraint. The natural foot can be quickly crippled into inefficiency by high-counters, corset-shoes, arch-raisers, wedges and elastic anklets. The natural foot, when burdened by misapplied mechanics, is rendered weak, and therefore susceptible of sustaining injury, such as sprains and the formation of bunions, flat foot, wobble joints, etc. The natural foot in a constitutionally weak or rachitic child may demand mechanical aids specially adapted to the individual requirements and peculiarities of the case. It is the duty of the medical profession to discourage the indiscriminate use of high-counters, corset-shoes, elastic anklets, arch-raisers and sole wedging, which are known to be injurious, unmechanical and productive of permanent loss of function."

**84. Elbow Fractures in Children.**—Cotton concludes his elaborate paper on this subject, which is too full to be abstracted, with a classification of the different forms of fracture, for which the reader is referred to the original.

**86. Suprarenal Extract in Urethritis.**—Eaton finds suprarenal extract of special value in chronic urethritis of the anterior urethra, characterized by glandular and follicular engorgement and by a tendency to epithelial infiltration and to form fibrous tissues. It may also be applied to posterior urethral inflammations of the same general character. In acute gonorrhea it is contraindicated. He reports cases.

**93. Gonorrhea.**—McShane holds that one attack of gonorrhea produces complete immunity to future similar attacks for a period lasting from a few months to a few years and that partial immunity modifying the attack may exist for an indefinite period; these cases of modified gonorrhea are sometimes mistaken, he holds, for reappearance of an old attack.

**95. Veratrum.**—The views of authorities on the effect of veratrum are noticed by Smith, who does not consider it an advisable remedy in pneumonia. While he has often used it, he has only been disappointed and never feels comfortable while employing it in this disease.

**102. Vomiting of Pregnancy.**—Wright considers the induction of abortion for the vomiting of pregnancy unjustifiable, as the natural termination of all cases is recovery. The resources of treatment are practically inexhaustible. If death occurs it is more likely to be due to gastric ulcer, malignant growths, tubercular peritonitis or some other disease.

**111. Prostatic Enlargement.**—Belfield summarizes his paper as follows: "1. Acute retention from prostatic enlargement is due to edema, not a rigid obstacle, in the prostate. 2. This edema can be passed sometimes by a Nelaton, always by a Mercier catheter. 3. A metallic catheter is curved to traverse the normal deep urethra and is therefore not adapted to traverse the elongated, distorted urethra of the enlarged prostate. Hence it should be used only as a last resort, and then never forcibly. It is understood that urotropin or cystogen should be administered at once in all cases of acute retention and continued until the danger of pus infection of the urinary tract has passed."

**121. Mammary Cancer.**—The modification of Halsted's operation here suggested by Binnie consists practically in doing the excision from without inward instead of from within outward. As much skin is removed with the breast as in Halsted's operation, but the ordinary incision penetrates the skin alone. The skin is reflected centrifugally from the tumor and more thoracic fat is taken away. If it is desirable to incise the supra-clavicular or cervical glands, such work would form

another step in the operation. The advantages claimed are: 1. The delicate axillary dissection is done while the surgeon is fresh and he is not hampered by loose tumor mass getting in his way. 2. The breast remains *in situ* while the tedious portions of the operation are being executed, preventing body cooling, and hence obviates some shock. 3. It has the advantage also of not requiring the assistant to manipulate the breast while the surgeon works in the axilla and thus possibly avoiding some chances of driving cancerous virus from diseased lymphatics and into the circulation before all communications are cut off.

**123. Skin Grafting.**—Turck believes in the preliminary use of oxychlorin, 1 to 500 in sterilized water, as a wet dressing on alternate days with aristol for a week or more. In the cases reported it was applied alone for three days before the grafting operation and left undisturbed until brought to the operating room. After removal of the wet dressing, the grafted surface should be rinsed with salt solution, shaved with a sharp scalpel and if any tissue seems soft and irritated it should be removed down to firm granulations; all blood clots and shreds are to be carefully cleared away. The grafts are cut with a sawing motion, taking a little less than one-half the thickness of the skin. Numerous small grafts one-half to three-fourths of an inch by one inch in size do better than a few large ones. They should be placed in no solution after cutting, but transferred immediately to the field. It is well, however, after the graft is cut, to dip the end of the razor into normal salt solution, thus taking a few drops of the solution on the concave upper surface to float the graft off. The advantage of overlapping grafts is doubtful; they should just touch one another, and a little overlapping does no harm. The wounds left from taking the grafts are dusted with aristol or dermatol and a layer of gauze covered with vaselin applied. The grafted surface should be entirely covered by narrow strips of rubber dam to prevent any adhesions of the outer dressing. Over these, layers of gauze wet with normal salt solution and the whole enveloped in rubber tissue or oil silk, forming a saline moist chamber. The dressing should not be allowed to become dry, but should be kept constantly moist, and the dressings be left undisturbed for several days. When removed the field should be carefully cleansed with oxychlorin solution, taking particular pains not to disturb the grafts and a wet dressing of oxychlorin applied. It should be left for two to four days. If after removal there appears to be no great amount of secretion, the field may be dusted with aristol and the daily alternation of aristol and oxychlorin continued for a week or more. After cicatrization is well marked, an ointment of aristol and vaselin should be applied until the scar is perfectly formed.

**140. Laparotomy Dressings.**—The following method is described by Dudley as that employed for abdominal incisions in St. Luke's and Wesley Hospitals: 1. Dusting with nosophen; 2, a single layer of gauze, its outer edge fastened down with collodion; 3, a layer of cotton; 4, a second layer of gauze fastened down with collodion; 5, several larger pieces of gauze secured by perforated adhesive plaster over all. The advantages of this method of dressing are claimed to be: 1. Nosophen powder, if freely used over the wound, is preferable to most of the other so-called "dusting powders"; and, especially when used in combination with the subcutaneous suture, is almost certain to prevent stitch-hole abscesses. 2. By using the collodion only on the margin of the gauze, any slight secretion from the wound, which, if confined, might embarrass the healing process, can escape by absorption into the dressings. 3. A small amount of cotton placed between the two layers of gauze adequately serves for absorption of wound secretions and for the protection of the wound against outside influences. 4. A small amount of gauze and cotton dressing may be used in place of the enormous and cumbersome dressings which are ordinarily employed and which are not only a source of great discomfort to the patient, but are with difficulty kept in place by the conventional abdominal binder, and which, moreover, may confine so much heat to the region of the wound that it acts like a poultice and so favors suppuration. 5. The perforated plaster takes the place of the annoying and rather unmanageable abdominal binder, which a careless or incompetent nurse not un-

commonly permits to slip upward toward the axillæ, thereby leaving the wound exposed. In a long series of cases at St. Luke's and Wesley hospitals, dressed in the manner above described, only one case has shown suppuration in the wound, and in this case the incision has been made through an old suppurating sinus.

**141. High Temperature in Children.**—The following "thermic aphorisms" are laid down by Hatfield regarding high temperature in children, its significance and management: 1. Transient high temperature (below 104) is of little clinical significance. 2. Barring cerebral lesions, continued high temperature is evidence of the accumulation and attempted destruction of toxins in the organism. 3. Except in rhaehitic children, this process is conservative and rarely requires other than hydropathic treatment. 4. The most prompt antipyretic for children is antipyrin in alcoholic solution given either by the mouth or rectum. 5. The safest antipyretic, though slow in its actions, is quinin by inunction or suppository. 6. An antipyretic that is analgesic as well as antithermic is acetanilid, best given in a dilute solution of arom. spirit. ammoniæ. 7. Phenacetin, as an antipyretic for children, is slow in its actions—at times, cumulative—and may be profitably substituted by lactophenon given in the same doses. 8. Pathognomonic temperature curves, on account of the nervous instability of the child, are less frequent than in adults, and this is especially true of typhoid, malaria and broncho-pneumonia.

**150. Preputial Adhesions.**—Cases are reported by La Fevre of convulsions, enuresis, mental depression and other neuroses in females, which were relieved after other methods had failed by breaking up adhesions of the clitoridian prepuce. He remarks on the neglect of this condition and, while admitting that it produces no symptoms in many cases, holds that it should always be borne in mind when a reflex neurosis, not otherwise explained, is encountered.

**161. Vesical Calculi.**—Wooten discusses his cases and gives his preferences. He thinks the suprapubic operation has its disadvantages in the lack of natural drainage and the impossibility of determining whether immediate suture is possible; the inability to regulate the extent of incision in bladder wall toward the pubis; serious post-operative complications such as suppuration, necrosis, etc. There is a danger to the peritoneum when it is anomalous and extends down over the anterior surface of the bladder beyond the usual limit. The long duration of convalescence is another trouble and hernia may occur even when the deep fixation sutures in the upper angle of the wound are employed. The disadvantages of perineal section are the dangers of sterility which Ehrmann characterizes as a bugbear and which are slight at best, and the inability to inspect the bladder and meet with other conditions than the existence of stone. The advantages are that the surgeon can thoroughly and usually ascertain by finger or forceps that the bladder is free from growths and debris and the existence of prostatic growths, the natural drainage by retention catheter and the chance of clearing up existing cystitis, the non-prevention of treatment of certain forms of prostatic growth and the chance of dealing with complications of stricture in the deep urethra, the possibility of using perineal lithotomy when stone is found to be unusually large and the statistical evidence in its favor. He finds, according to the records which he has been able to obtain from Cabot, White, Barling and others, that the percentage of deaths is much less in this operation than in the others.

## 2. Myelocene in Deafness.—Watson offers the theory that

bone marrow produces an internal secretion of vital importance in the economy and that it is a powerful prophylactic against the injurious action of various bacteria which in health are present as saprophytes in different tissues and that defects in this bone marrow are likely to be followed by pathogenic action of the same micro organisms. The results of this pathogenic activity vary with the individual reaction. The main sites of these bacteria are the respiratory and alimentary tracts and the skin. In this article he deals with chronic suppurative middle-ear disease and promises in a later one to give the results of

observation in cases of psoriasis. As a sort of control experiment he uses olive oil as a mechanical lubricant and the combination of rectified spirits and glycerin on account of its stimulating effect on the circulation of the membranes of the middle ear. Having satisfied himself as regards the effect of mere lubricants, he proceeded to apply the substance derived from the bone marrow according to his theory and gives the results in 20 cases. The tests mainly included the watch, whisper and ordinary voice, the latter being the one which he found most satisfactory. Of the 20 cases treated, 4 were of a mixed type, the tuning-fork conduction being greater by air than by bone. One case was of post-suppurative origin. The results are summarized as follows: "Of the 15 cases of apparently pure dry middle-ear disease, 11 showed a record of improvement fairly comparable to those already detailed, due allowance being made for the different degrees of deafness when the patients first came under observation. Two showed a marked improvement in one ear only, but as this improvement took place in the deafer ear, the practical benefit was slight; 2 cases, male patients aged 46 and 60 respectively, were uninfluenced by the treatment. Of the mixed cases 3 showed a practical improvement and one did not. The post-suppurative case improved. In some cases the improvement has been fully maintained, in others deterioration has set in slowly and progressed. Observations are at present being made on means of maintaining the improvement in the hearing power." It may be said here that there was a temporary improvement following the use of rectified spirits and glycerin. Olive oil was ineffective. The substance employed, which he calls myelocene, is prepared as follows: The bone marrow from selected normal bones with perfectly physiologic appearance is extracted with ether and the ethereal solution is evaporated down at first in the open and later over the warm bath. The fat is then rubbed up with 1 per cent. chloretone for preservation. It now appears as a whitish or faintly yellow fat with a strong odor, partly of ether, partly of chloretone, with a variable melting point. The fat with a low melting point is the only one that has proved satisfactory in use.

**4. Isolation of Typhoid Bacillus.**—The separation of typhoid from the colon bacillus in examination is often a matter of some difficulty, the latter being uniformly present in overwhelming numbers in any material likely to be contaminated with the typhoid bacilli. Moore first experimented with a W-shaped tube, using the Parietti serum gelatin, in which the material was introduced in one limb and the actively motile typhoid bacillus passes through it to the other, while the sluggish colon bacilli remain at the bottom of the first curve. This, however, while giving excellent results in artificial mixtures with a given strain of colon bacilli, was unsatisfactory for other strains. To meet this objection he used a modification of the Elsner potato iodid gelatin medium, which itself is slow in action though otherwise the best process, substituting agar-agar for the gelatin. Plates prepared with this medium were sown with mixed cultures of typhoid and colon bacilli and incubated for 24 hours in an incubator at 37 C. At the end of this time examination under a low power microscope shows very much the same difference between the two sets of surface colonies as is found in the Elsner gelatin after four or five days' growth, the typhoid colonies being very clear, transparent and almost invisible when strongly illuminated, and with irregular clean-cut margins, while the colon colonies were much larger, rounded and opaque. In this way the typhoid bacilli were isolated in pure cultures from numerous artificial mixtures, especially from Thames water contaminated with typhoid broth culture and old dejecta kept for five months.

**5. Typhoid Fever.**—Gibbes offers the following as a new point of diagnosis in typhoid, viz., the use of photography, which reveals the rose spots much earlier than the naked eye can recognize them. The best plan is to use orthochromatic plates and make a number of exposures as quickly as possible; a ray filter is required with some plates, but with Cadett's "spectrum" plates, this would not matter. The procedure is simple; cover the head and face with a light shawl and remove the covering from the abdominal regions, moisten a small bit of printed matter, and stick it on the skin to get the focus.

The operation is greatly facilitated if an assistant throws all the light possible on the part by a mirror. No rules for exposure can be given, as the light varies, but out of six exposures of varying light one or two should show the rash. The greatest care is required in developing the plate. Over-exposure must be avoided and development should be slow, with a weak developer and not carried too far.

**11. Typhoid Fever.**—This first Milroy lecture by Corfield is historic, giving the history of the development of the theories of typhoid to their final verification by the discovery of the typhoid bacillus.

**12. The Pulmonary Circulation.**—Brodie's experiments by the plethysmographic method on the lung brought out a number of facts in regard to its circulation, some practical deductions from which are made on the effects of certain drugs. He doubts whether there are vaso-constrictor fibers to the pulmonary arteries. He finds that his experiments rather contraindicate the use of adrenalin or suprarenal extract in case of pulmonary hemorrhage. Still, the results are not conclusive, as the effect of small doses taken internally is still to be considered. It seems to have a directly opposite effect on the pulmonary vessels from what it has on the systemic, when applied by perfusion in the vessels. The action of nicotin is somewhat similar to that of suprarenal extract, producing congestion of the lungs and rise in pulmonary venous and arterial pressure. Pilocarpin tends to produce systemic vaso-constriction, the effect of which, however, is obscured by marked cardiac inhibition simultaneously produced. Muscarin produces the same effect as pilocarpin.

**14. Staphylococcal and Streptococcal Infection.**—Bellei reports several cases of interest, two of fatal staphylococcal infection. The first was a man who was infected while operating on an abscess in a woman and pyemic abscesses resulted. The infection of the woman was not severe and she recovered. The second case was that of a boy who died in six days from a slight injury by a nail in the right leg. The streptococcal cases reported are of interest from the fact that in one there was a complicated infection with streptococci and saccharomyces, and he suggests that the natural defense, the phagocytes, were inefficient on account of the presence of the saccharomyces, though they might have been efficient if the streptococcus had been alone. Both patients had suffered for many years from disease of the teeth, with pus formation, and he suggests the ill effects following were largely due to this original infection. The micro-organisms which exist in the saprophytic state in the mouth become virulent when chronic disease of the alveoli and gums is present.

**15. Electric Shocks.**—A good deal of misapprehension exists as to the circumstances under which shocks at 500 volts may be felt or conditions which may lead to serious consequences. The electric pressure of 500 volts has become well established as a standard for electric traction, but pressure can be arranged to take another 100 or 150 without appreciable alteration. Conditions of commercial standardization seem to set the limit of working at about 600 volts. It is fortunate that no further extension of pressure is likely to be wanted. Since in a few cases 500 volts have been fatal, it has been assumed that they always are. But Trotter says that he has repeatedly stood on rails in wet boots, sat on rails and slapped the running rails with his bare hand. A pressure of 300 volts was used at first for traction purposes, but afterward it was found by Americans that 500 volts were high enough for economy and not too high for safety. The sensation of 500 volts may be a prick, a pleasant tingle, a hot burning or a convulsive shock. It does not depend directly on the actual current, but on the current density. With four or five square inches of contact between dry metal and bare skin, a steady continuous current of one or two milliamperes is hardly perceptible. From 3 to 8 are easily supportable, above 10 painful and above 35 almost unendurable. With larger currents and more surface, muscular contractions are added to the tactile sensations, especially if the current is at all unsteady. The alternating current seems to be four or five times more painful, but the sensation

is of a different character. It is difficult to make any exact determination between the current density and the sensation. More than about 14 milliamperes of steady continuous current at the finger-tip, making a poor contact of about one-sixth of a square inch, is unendurable, but 35 milliamperes from boot to boot, nearly the whole soles of the feet in contact, is much less painful. The resistance from hand to hand when grasping two pieces of dry trolley wire is about 5000 ohms, and he has found it as high as 14,000 ohms. The resistance between the body and earth or an iron rail through the sole of the foot, stocking and rail is of considerable importance. He finds the resistance from boot to boot, the boots being free from nails, varies from 45,000 to more than 200,000 ohms. The lowest measurement he observed with 500 volts was 25,000 ohms. Boots worn into holes and wetted gave 13,000. The mere touching of dry metal at 100 volts gave hardly any sensation, but with a larger contact the shock is severe. At 200 volts a light touch gives an unpleasant prick, but the current through a firm contact is from about 12 to 18 milliamperes, which can be borne without considerable pain. The sensation is very similar to that of heat. To grasp with bare hand two pieces of metal at 500 volts may give a very painful shock, but a light and quick touch is no worse than that from a half-pint Leyden jar. A 500 volt may be described as worse than touching a kettle of boiling water, but not so bad as touching a red-hot poker. Such shocks are common occurrences with careless linemen. Cases of fatal accidents from 500 volts are so rare that the condition can only be guessed at. If the skin resistance be reduced by moisture, especially if salt or chemicals be present, and if the contact be long and pronounced 100 volts may be fatal, but a man may be choked by a crust of bread under exceptional conditions. Neither the man in the street nor a man on a car runs any risk of taking 500 volts, skin to metal. Trotter has repeatedly done this and had no trouble, and his son, 7 years old, stood on a rail and played with a wire of 500 volts. The current was less than one-quarter milliampere, and he felt nothing. A fallen telephone wire is not so easily seen. It does not stop traffic and may twist around a person and burn him. With wet boots and wet ground the conditions are worse. The danger of the third rail on the electric railways is also mentioned, and he remarks that the effects are about the same as in the other case. Horses are especially susceptible to shock. What would be a painful shock to a man can cause instant death to a horse. Horses are terrified by conditions where a human being would feel no shock. It is possible that the resistance is very small and the current large. The horse is specially fitted for making contact with his shoes, which are connected by nails with his body. The conclusions are given as follows: "The dangers of electric shocks at 500 volts have been much misunderstood, greatly exaggerated and little investigated. The pressure of 500 volts has been deliberately chosen by electrical engineers because it is not dangerous under ordinary conditions. The conditions under which serious shocks are not produced by 500 volts are discussed in the paper, and it is safe to assume that all shocks more serious than those which are recorded are dangerous. Dry wood and dry boots without large nails offer so great resistance to electric current that it is perfectly safe to touch a trolley-wire while standing on a dry tram-car, or even while standing on the ground or on the rails. Wet weather makes a considerable difference, but boots must be very wet to allow enough current to pass to produce a severe shock. Men engaged in electric traction work receive many slight electric shocks at 500 volts and they might avoid most of them by taking more care. Dry clothing offers so great a resistance that no shock can be transmitted through it. The peculiar conditions under which shocks at 500 volts have caused death are discussed and are shown to be very exceptional. Experiments have been made on some 30 persons, including 12 women and 6 children, and it is proposed to make other experiments. With sound dry boots hardly anybody can feel a shock when standing on the live rail of an electric railway with one foot and a running rail with the other. With damp or wet boots a shock is felt, but neither the sensation nor the degree of wetness of the boots can be measured accurately. It is not

possible to receive a shock by sitting or lying on a live rail so long as the clothes are dry and continuous—that is to say, so long as the live metal is not touched by the bare skin."

**17. Latent Malaria.**—Moore suggests conditions analogous to those described in certain plants, as occurring in malarial parasites. He has observed certain bodies which seem to him to be able to take a simpler form of reproduction than the ordinary one. In his observations of latent cases which he reports, the duration varied from a few months to several years, and he thinks it depends upon the following, viz.: 1. The parasite failed of development in sufficient numbers to liberate toxins and cause symptoms. 2. The parasites may become attenuated to such a degree that they do not produce the amount and the kind of toxins to manifest their presence, for they may be present in large numbers, as he has frequently observed. 3. The individual may have acquired a certain immunity, so that he prevents sufficient development of parasites which liberate toxins or the organism has become more resistant. 4. The attenuation, lack of development and partial immunity may have been of such a character that the symptoms manifest themselves in an atypical way, or the presence of some associated disease may so modify the symptoms of malarial fever that they become atypical. In this case he would be disposed to speak of it as a masked rather than a latent malaria.

**22. Uncinariosis.**—Bancroft believes that he has observed cases where reinfection with ankylostoma was produced through the skin by children walking through infected ground. He reports a case and the conditions which would favor this method of infection and gives Looss' statements in bearing out this theory. He notices that children or persons affected with ankylostoma are inclined to eat dirt and gritty materials and thinks that a feeling of well-being is produced by such ingestion, possible dislodging the parasites in the bowel.

**23. Antitoxin.**—Paton has used diphtheria antitoxin for septic conditions, giving it internally, and says that its range of action is: "1, specific for the staphylococcus and streptococcus in all their varieties; 2, specific for simple and traumatic inflammation (whether we regard such inflammation as being a distinct entity or only an attenuated sepsis, diphtheria antitoxin makes no distinction); 3, without parallel in medicine as an absorbent of inflammatory tissues left from the previous-mentioned inflammations, 1 and 2, and also of effused blood; 4, that it has considerable influence on the coagulability of blood, and 5, has great power in some depressed nervous conditions, probably due to septic conditions acquired or to autotoxemia." Though he can not say how it acts he is satisfied that it has a beneficial effect. The gastric secretion, he holds, from such data as he has obtained, has little effect on antitoxin. He believes the oral exhibition of glandular and other organic products, such as thyroid and suprarenal, is sufficiently a parallel to justify the exhibition of antitoxin serum in this way. His formula for using it is given as follows:

R. Diphtheria antitoxin, 3000 units.

Trag. carmin q. s.

Aq. ad ..... 3ii

M. Sig.: Dose one half ounce (which equals 750 units).

The time of administration varies from night and morning to every 4 hours, but the latter is only used in exceptionally severe cases; it is better to give too much than too little. For erysipelas 3ss every 8 hours is usually effective. For acute peritonitis and appendicitis 3ss at once, 3ss in two hours, 3ss four hours later, and afterward every 6 to 8 hours now usually does all that is required. For children the full doses may be given, as the antitoxin is harmless, but usually for small children half the dose is quite effectual. In about 1 per cent. of the cases either a little kidney irritation or skin eruption may be seen, but they are of the most superficial and fleeting character."

**27. Alopecia Areata of Dental Origin.**—Jacquet regards alopecia areata as a symptom resulting from various irritations. The most common of all these irritations is from the teeth. He has established in numerous instances that the alopecia has developed subsequent to a subjective series of phenomena in the sphere of the inferior trigeminal. The

localization of the alopecia is on the same side, and it is merely one factor in the syndrome of sympathetic manifestations grouped around the primary trigeminal phenomena. The cause of the syndrome is some irritation of the gums or teeth. The study of the routes of conduction clearly explains the connection between the initial irritation and the cutaneous symptom as well as the entire pathologic train. Suppression of the primary irritation entails the disappearance of the symptom-complex derived from it. He has established this train of phenomena in 27 out of 200 cases of alopecia areata and reports 21 in detail, with diagrams illustrating the routes of nerve conduction and the close connection between the dental or parodontal affection and the alopecia. He noted painless congestion in one case, painful congestion or congestive neuralgia in 7 and simple neuralgia in 19. The syndrome may include epistaxis, coryza, erythrosis, hyper- or hypo-thermia, adenopathy, swelling of the tonsil—all on the same side and connected chronologically and topographically with the alopecia and all with a substratum of latent and deep hyperesthesia of the nerves and muscles or of the former alone, most marked at their emerging points.

**29. Chloroform in Heart Disease.**—Panas attributes sudden death under chloroform to a bulbo-laryngeal reflex contraction of the vocal cords, from contact of the fumes with the glottis. This contraction prevents the passage of any air and even of the chloroform into the lungs. The mechanical phenomena of respiration on the part of the ribs and diaphragm continue as usual and deceptively simulate normal respiration in spite of the asphyxia. The heart soon ceases to beat and the death is erroneously attributed to the cardiac syncope, when in reality the contraction of the vocal cords was the primary trouble. In blue asphyxia the heart and the pulse persist and the thorax rises and falls normally. But the intoxication from the excess of carbon dioxide in the blood superimposed on the disturbances from the anesthetic, entails such a condition that it is impossible to resuscitate the patient. In both these cases the respiration and the heart action continue approximately normal until the danger point is long past. The anesthetist should devote his chief energies to surveillance of the free intake of air. He should listen closely and continuously to hear the laryngo-tracheal respiratory souffle. A useful precaution is the addition of an index to the receptacle holding the chloroform. Any disturbance in the regularity of the to-and-fro movements of the index should sound the alarm and the anesthetic should be suspended until respiration is restored to regular and complete action. Panas emphasizes that by observing these precautions there will never be any deaths from chloroform, even among patients with established heart disease. He has performed 15,000 operations and has never had a mishap. The reason why children take chloroform so much better than adults is because they protest against and resist the chloroform, cry and scream and in their excitement take deep breaths. This prevents the spasmodic closure of the glottis and enables the anesthesia to be complete with the minimum of chloroform. The persons for whom chloroform is inclined to be dangerous are not those with heart disease, but nervous persons with peculiarly intense reflexes easily induced and long persisting. Such patients require the closest surveillance; the chloroform should be administered drop by drop and suspended at the slightest suspicion of irregularity in the breathing.

**31. Sudden Death of Gastric Origin.**—Lancereaux affirms that two-thirds of the cases of sudden death in which the organs are found sound, are the result of reflex inhibition of the centers of circulation or respiration by a nervous disturbance in the stomach, usually due to dyspepsia and most frequent in dyspeptic subjects with a gouty taint. The digestive disturbances excite the heart, especially if there is dilatation or fatty deposit in the organ. Sudden death from this cause occurs at the time after meals when the digestive troubles are at their height, at night between 2 or 3 a. m., in the afternoon between 4 and 5. He describes several instructive cases in which he was able to resuscitate the patient by artificial respiration, but the syncope recurred again and again. In one there were no other symptoms except slight colic, nausea and vomiting, but

the syncope kept recurring and at last resuscitation was no longer possible and the patient died. The trouble began four days before with an indiscretion in diet, which had been followed for three days by vague dyspeptic disturbances and accelerated pulse. Death was undoubtedly due to arrest of the heart action. The physician with his finger on the pulse was able to foretell the approach of the syncope each time. It invariably commenced by the total disappearance of the pulse, followed by contraction of the jaws, rigidity of the muscles of neck and thorax, stoppage of respiration and apparent death, which would have been actual death if artificial respiration had not been practiced at once. Stimulation of the nerve terminals in the mucous membrane of the stomach induces the inhibition of the bulbar reflex center and hence arrests the heart. Death from this cause is frequent. Hillairet and Potain are examples of it. Neither had any organic affection of the heart or arteries and both retired at night in good health and were found dead in the morning. The prophylactic indications are to treat the dyspepsia and moderate the excitability of the nervous system. The majority if not all of such subjects are impressionable nervous persons, leading a more or less strenuous life and digesting poorly. In the presence of an attack, artificial respiration should be practiced, the patient reclining and the head low, the heart stimulated and the excitability of the bulbar center neutralized by abolishing reflex action as far as possible. This can be accomplished by the proper dose of morphia, but too weak a dose exaggerates the reflexes and too strong a dose is toxic. The physician must individualize for each patient and for the origin, the nature and the intensity of the trouble in each case. The initial excitation may be moderated when it proceeds from the stomach by leaving the organ in repose, allowing nothing except possibly water with sodium bicarbonate. Digestive disturbances in the intestines are liable to induce sudden death in this way the same as when located in the stomach. Instances of this are not rare in convalescence from typhoid fever or dysentery.

**33. Heredity in Relation to Movable Kidney.**—Guillet thinks that movable kidney should not be considered a malformation or a sign of degeneracy, as some maintain. In a few exceptional cases it is possible that a general tendency to looseness and laxness of the tissues may be inherited. In other cases the condition is acquired. The shape of the paravertebral recess in which the kidney lies is peculiarly adapted in women to favor the production of movable kidney under slight provocation.

**35. Insanity in the French Army.**—Granjux states that the proportion is about .4 to 1000 men. This proportion is doubled in the troops stationed in Africa, quintupled in the prisons and sextupled in the "compagnies de discipline."

**36. Lactate of Mercury in Treatment of Syphilis.**—Gaucher asserts that the neutral lactate of mercury is of all the mercurial salts the one best adapted for the treatment of syphilis, either by the mouth or in subcutaneous injection. It is prepared by dissolving the red oxide of mercury in 10 per cent. lactic acid. The salt thus obtained belongs to the organic series; it is easily made and of almost indefinite stability; it is scarcely at all irritating and contains so much mercury that 1 cg. a day in a subcutaneous injection is an ample dose.

**37. Prokhoroff's Method of Treating Syphilis.**—Scherb has been testing this method of treating syphilis and describes three cases of severe and old encephalopathy and myelopathy remarkably benefited by this treatment, which is based on the principle that mercury which is frequently toxic in repeated small doses is not so in large doses at sufficient intervals. Each case had been rebellious to ordinary mercurial treatment. One was so far advanced that the benefit was only transient as the patient soon died. He injected in one case of syphilitic general paralysis 18 cg. of the salt and the same amount 12 days later and 12 cg. after another interval of 14 days. The acute paralytic manifestations subsided in less than a year and the improvement amounted to resurrection. Another patient with the "cerebellar syndrome" and atrocious cephalalgia was completely cured after three epidural injections of the same amounts at ten-day intervals. There was a slight pollakiuria,

due probably to some irritation of the nerve rootlets innervating the bladder and urethra.

**38. Relations Between the Spindle-Spirillae Symbiosis and Diphtheria, Etc.**—Simonin relates a number of clinical experiences to sustain his assertions that the symbiosis of the spindle-shaped bacillus and spirillae (Vincent), is of great importance in pathology. These parasites are superficial and not toxic. They never invade the general circulation and are never found except in some cavity in direct communication with the mouth. Their action is restricted to boring a passage through the skin or the mucous membrane. But the boring of these passages provides an entrance for germs capable of causing dangerous secondary septicemia and consequently the spindle-spirillae combination is a menace. Every cause altering the pharyngeal epithelium favors the implantation of the associated germs, but they are easily destroyed by simple antiseptic measures.

**40. Pathogenic Deductions from Freezing Point of Hydatid Fluid.**—Surmont found that the freezing-point of hydatid fluid is about the same as that of the lymph. The hydatid membrane is evidently permeable in both directions for crystalloid and colloid substances. These facts explain the slight amount of molecular interchanges between the parasite and its host and also the phenomena of intoxication which supervene after violent osmotic exchanges, such as occur after puncture and partial evacuation.

**41. Study of the Diazo Reaction.**—Deléarde is convinced that the diazo-reaction is not produced by absorption of the products of intestinal putrefaction, as the ingestion of powerful antiseptics, such as the saline purgatives, do not diminish it. There is no proportion between the amount of indican in the urine and the intensity of the diazo-reaction. On the other hand, the reaction diminishes or is completely suppressed under the influence of the phenol group, phenol, salol, benzo-naphthol and betol. This effect is evidently due to the action of the phenol on the substances in the urine which induce the diazo-reaction.

**42. Relations Between Cutaneous Affections and the Size of the Stomach.**—Butte noted that the size of the stomach was larger than normal in cases of eczema, herpes, psoriasis, acne, urticaria and alopecia in his experience. Assuming that the normal adult stomach measures 8.5 to 10 cm. vertically and 9.5 to 11 cm. horizontally, the increase in size is evident in the list of 34 cases he publishes. The size also parallels the extent and intensity of the cutaneous affection. In a case of eczema for instance, the stomach measured 11x14 cm. and subsided to 10x12 when the eruption vanished. In another case, from 12x17 the stomach subsided to 9x11 as all traces of the eczema disappeared. In a case of chronic eczema of the nails the stomach measured 12x20. Among the cases of herpes was one with 12x15 during and 10x12 after recurring herpes. One patient with alopecia, 13x17, and only 9.5x14 as the alopecia subsided. One with urticaria, 10x15 during and 8x11 after the attack. One with acne of the face for 6 years, 12x16 and 10x14 as it healed. In seborrheic eczema and psoriasis alone, the size of the stomach did not diminish during recovery from the cutaneous affection.

**43. Hysterical Vomiting in Children.**—Carrière describes two cases of severe repeated vomiting in girls of about 9 years of age. There was no organic lesion. The vomiting had been preceded by other neuropathic manifestations, somnambulism, arrhythmic chorea, etc. It did not affect the general health and could be induced, modified and even suppressed at times by purely psychic causes. A hysterical origin was consequently probable, and both of the children were promptly cured by a catheterization of the stomach. Other practitioners have been successful in such cases by administering methylene blue pills or some other impressive measure, by suggestion under chloroform, by hypnosis, and Basset actually performed a laparotomy.

**44. What We Can Learn from Homeopathy.**—Bonnier is a converted homeopathist, although he only confesses that he studied homeopathy from curiosity. He thinks that certain of its principles, revised and corrected, may be studied with profit by every physician. He claims that among these principles

are: 1, the necessity of thorough study of the drug to be used; 2, that a drug should not be combined with other less known drugs without good cause; 3, that the dose should be as small as possible; 4, that masked expectant treatment should be sometimes raised to an actual principle; 5, that the diet should be strictly supervised, with what might seem at first view to be almost puerile regard to details; 6, that the possible opposition of the effects of the same drug at different doses should never be forgotten; 7, utilize the *similia similibus, alias* substitutive method, for whatever it can possibly accomplish.

**46. Lumbar Puncture for Cephalalgia.**—Carrière states that intense cephalalgia in 4 cases of tubercular meningitis in his service ceased after lumbar puncture. The fluid was under very high pressure; moderate pain recurred later in 2. The same procedure relieved the intense headache in a case of acute, fatal hydrocephaly. No relief was obtained in a case of empyema of the frontal sinuses. The cerebrospinal fluid flowed very slowly in this case. In another of uremia with intense headache, the cerebrospinal fluid flowed very slowly and the intervention was ineffective, but in a second case the fluid was under high pressure and the cephalalgia disappeared permanently after withdrawal of 90 c.c. In 2 patients with migraine, there was no improvement after lumbar puncture in one, and only a small quantity of fluid could be withdrawn. In the other the puncture allowed the immediate escape of 50 c.c. and the attack was arrested at once and without vomiting. It proved ineffectual in 6 cases, one a chlorotic patient, the others with adenoids. These results indicate that the headache in one class of cases is due to hypertension of the cerebrospinal fluid and is relieved by evacuation of a certain amount. When it is the result of some organic or functional disturbance of the brain or vasomotor action, it is not amenable to lumbar puncture. Carrière has but once witnessed headache occurring after the lumbar puncture. That patient, instead of reclining afterward, according to instructions, walked home and suffered from intense headache for twenty-four hours, probably from the motion and upright position. When the previous cephalalgia persists after the lumbar puncture its characteristics remain unaltered.

**50. Direct Surgical Intervention for an Aneurysm of the Aorta.**—Tuffier observes that an aneurysm of the arch of the aorta can not be reached by the surgeon when it is located in the descending portion. It can not be isolated when it is very large and adherent to all the organs of the mediastinum, and it would be impossible to extirpate it in case of total ectasia of the artery or if too large an extent of wall is involved. As these three varieties of aneurysm are the most numerous, only a limited number at the best are amenable to surgical intervention. The degeneration of the wall observed at the autopsy in case of ectasia of the artery does not necessarily affect the intervention, as the part involved in the sac dilatation is the only part that ruptures. Sac-shaped aneurysms are therefore the only ones that indicate surgical intervention, and only those in which the moderate size encourages the hope of complete obliteration by the procedure. The diagnosis of this variety is possible with radiography; resection of the sac with lateral suture of the vessel is easily done and promises to be effective, although cases of this character are very rarely encountered. To justify operation they must be accessible and possible to isolate and extirpate. They must be the only arterial lesion and beyond the reach of medical aid, threatening a speedy fatal termination. He recently found these conditions united in a woman of 40, free from syphilitic taint, with an extremely painful pulsating tumor with synchronous pulse, both radial and temporal, on both sides. Its location indicated that it must be an aneurysm of the ascending portion of the arch of the aorta between its origin and the emergence of the brachio-cephalic trunk. The slowness with which the aneurysm filled again after it was reduced, the absence of concomitant aortic insufficiency, the normal position of the arch of the aorta, and the single souffle, suggested a sac-shaped aneurysm with a narrow neck, rapidly increasing in size. It had only to ulcerate the skin to perforate outward, and had attained the size of a fist. There was no sign of any other arterial

lesion and the general health of the patient was perfect. Although fully informed in regard to the danger of an operation, she clamored for it as the radiating pains from the aneurysm were unbearable. Tuffier examined all the specimens of aneurysms that he could find in the museums and found seven which corresponded to his conception of the aneurysm in the present case, and indicated that they could have been successfully extirpated. The sac was found as he anticipated, but it was adherent to the second and third ribs and to the pleura. The second rib was actually imbedded in the tumor, and he cut it across on each side, not venturing to disturb the adherent portion. After the sac was emptied into the aorta, the opening was found only large enough to admit the forefinger and a ligature was thrown around it. The pulse and respiration showed no disturbance. He intended to remove the empty sac and suture the wall of the artery, but omitted to do so at the last, and replaced the flap and sutured the skin wound. The immediate results of the intervention were most satisfactory, but the patient succumbed in a few days to secondary hemorrhage from the sac which had gangrened. The conditions found at the autopsy were all favorable to the healing of the wound if the sac had been removed as first intended. The walls of the aorta around the neck of the sac were nearly normal, and a suture would probably have held firm.

**51. Symmetrical and Ignored Fractures of the Clavicles.**—Féré gives the skiagraphs of five out of six persons distinguished by the fact of a complete fracture of both clavicles at the junction of the outer third with the inner two-thirds. Velpeau described a similar case and regarded the fractures as congenital. In only one of the six were any functional disturbances noted, and most of the patients had served as porters or something of the kind requiring the carrying of heavy weights. Féré's cases were all in his service for the insane at Bicêtre. He believes that such symmetric fractures are probably congenital and are due to violent muscular action in some intra-uterine convulsion.

**52. The Segment of Intestine Above an Intestinal Stenosis.**—Patel states that the walls of the intestine above a stricture are very often abnormally thick. This thickening is not proportional to the site, degree or age of the stricture, but always seems to coincide with some actual lesion of the mucosa. It consists of a pathologic infiltration of the muscle whose fibers are separated and dissociated, the infiltration involving and being most marked in the subserous and submucous cellular layers. This enlarged segment is diseased and should be sacrificed during an anastomosis, in order to operate entirely in sound tissue.

**53. Nasal Vertigo and Epilepsy.**—Jousset adds two more cases to the few on record of epileptic seizures with a nasal aura. The patient first experienced a tingling in the nose, followed by a heaviness in the head, formication and loss of consciousness. The face was at first congested and then became pale at the height of the seizure. In one patient there was a traumatic deviation of the nasal septum to the left, and in the other, rhinitis with hypertrophy on one side and atrophy on the other. Operative treatment of the abnormal nasal conditions led to the complete disappearance of the epileptiform seizures. He asserts unconditionally that the nasal conditions in these cases evidently were a prominent factor in the development of the seizures.

**54. Benefits of Surgery for the Mentally Unbalanced.**—Glénard cites the case recently communicated by Picqué in which a patient with anxious melancholia was operated on for the relief of recurring appendicitis, and was cured of the mental troubles at the same time. In a recent case the removal of a previously nephrotomized kidney cured a severe psychosis. Christian has also reported a case of delirium which was permanently cured by an urgency operation for the relief of a strangulated hernia. Glénard believes that operative intervention on the mentally unbalanced should not be limited to urgency operations, but should be undertaken deliberately in certain cases as an indirect means of influencing the nervous system. Picqué has collected 132 operations undertaken not

for the purpose of curing the mental trouble, but in response to general surgical indications. In 51 the mental trouble was cured at the same time as the surgical affection; in 21 the mental condition was much improved; in 42 unchanged and 8 patients died. The mental affection in similar cases, far from being an obstacle, should be an additional incentive to prompt surgical intervention, as it may accomplish the cure of two affections at once.

**55. Is There a Renal Diabetes?**—Munch observes that it seems to be established in experimental pathology that we are justified in admitting the existence of a glycosuria of renal origin. In certain cases, as an intoxication by cantharidin or after administration of theobromin, there is merely an increase in the permeability of the kidney. In other cases, as in phloridzin glycosuria, we may attribute to the kidney an actual sugar-producing rôle. These facts seem to be established in regard to animals, but there is much less certainty about them in human pathology. In all of the few cases that have been related the coincidence of sugar and albumin was certain. None of them afford positive evidence in regard to the relations as to cause and effect between the glycosuria and alteration of the kidney. It is impossible to class as renal diabetes any cases in which the renal affection did not unmistakably precede the glycosuria, or in which another cause can be incriminated such as gout or lithiasis, in the production of the glycosuria. Lépine has reported a case in which a woman of 69 died in coma with a glycohememia of 10.6 per cent. and atrophy of the kidneys. Achard and Weil have also published the case of a diabetic whose glycosuria diminished after an apoplectic attack while the hyperglycohememia increased. Such cases as these indicate that the permeability of the kidney plays a certain rôle, if not in the production, at least in the elimination by the kidney of the sugar in the blood. The reality of a renal diabetes has yet to be established, but in the meanwhile it seems to be possible and even legitimate to assume the existence in diabetes mellitus of an actual renal element.

**75. Compulsory Notification of Tuberculosis.**—Fraenkel advocates compulsory notification of tuberculosis when there is danger for the environment from the sputa, etc. He states that as long as this is neglected the campaign against tuberculosis lacks a most important aid. He observes that those who are quick to read the signs of the times are convinced that tuberculin is rising like the phoenix from its ashes and heralds a new era in the treatment of tuberculosis.

**76. Etiology of Carcinoma.**—Feinberg has been studying cancer tissue for years, frequently making a thousand sections in every direction of a single carcinoma. He calls attention to the vacuoles observed in it when stained by the ordinary methods. These vacuoles or minute cysts have been supposed to be merely interspaces between the cellular elements of the tumor, when any attention has been paid to them. He has succeeded in demonstrating by new methods of technique, that these assumed vacuoles are in reality micro-organisms independent of the human tissues. They have a membrane with a double outline which takes an intense stain with orange G. They contain a nucleus surrounded by an unstainable clear zone and a plasma which does not take the nucleus stain. He says that the cancer tissue must be very fresh, untreated by disinfectants and not crushed during the operation of removal. He found mammary cancer the best adapted for the study of these micro-organisms as it is usually operated on at an earlier stage than internal neoplasms. He proclaims that these unicellular organisms are probably involved in the etiology of the tumor, and that their discovery will differentiate a dubious new growth. The encysted form in which he has found the micro-organisms is probably not the form under which they invade the tissues primarily. He describes his technique in full.

**80. Intravenous Injections of Colloid Silver in Septic Affections.**—Mueller's experience with a 1 per cent. solution of Credé's colloid silver or "collargol" has been so successful that he regards it as an actual specific in septic affections. He has thus treated 30 patients, in threatening erysipeas, pneu-

monia, epidemic cerebrospinal meningitis, phlegmonous erysipelas, puerperal perimetritis, pleurisy with effusion, peritonitis, appendicitis, empyema, etc. One or two injections arrested a felon and phlegmons. In a case of acute articular rheumatism fourteen days of salicylic medication had been ineffectual in arresting the disease, which was accomplished by two injections of the collargol. He injected it five times in an emaciated girl of 9 years, who was in a very bad condition as the result of a tubercular affection of both knees, which had required resection and removal of sequestra. The fever vanished after the injections of collargol and the wounds healed rapidly. Although he has injected as much as 2.5 gm. and even 5 gm. of the collargol solution, he has never witnessed any evil effects except the chill, which occurs in almost every case one to four hours after the injection.

**82. Mechanism of Production of Albuminuria by Egg Albumin.**—Ascoli relates experiments which demonstrate that the white of egg in moderate amounts causes no albuminuria in healthy individuals, although its presence in the blood may be disclosed by the biologic serum test, which also serves to differentiate it from the albumin normally in the blood. After excessive amounts of the egg albumin have been ingested or injected subcutaneously, it succeeds in passing the renal filter and induces albuminuria. When this occurs the urine is found to contain not only the egg albumin but also the albumin which is the normal constituent of the blood. He explains this by assuming that the kidney is relatively immune to albumin in small, physiologic amounts, but that it is injured by large amounts. The resulting lesion allows the passage of the egg albumin and also of the normal blood albumin.

**83. Danysz's Bacillus.**—Wiener announces that the virulence of the Danysz bacillus can be enhanced by cultivating it in raw eggs. It is then capable of inducing extensive epizootics among rats. He injects 8 or 10 drops of a 1 per cent. solution of soda into a freshly laid egg and then introduces a loopful of the bacillus culture. The contents of the egg become transformed in the course of eight days to a highly virulent, practically pure culture, killing rats in five to seven days. Other rats fed with the intestines of the dead ones, succumbed even more rapidly. It was impossible to induce infection of fowls and rabbits even with these highly virulent cultures.

**84. Bactericidal Action of the Roentgen Rays.**—Rieder's tests have confirmed the bactericidal power of the Roentgen rays. It is not energetic enough to be a very prominent factor in their therapeutic application. The efficacy of phototherapy is due rather to the "reactive inflammation of the skin" determined by it.

**85. Internal Use of Chloroform and Its Dangers.**—Frank reviews 7 cases of ingestion of chloroform for the purpose of suicide and 14 in which it was taken by mistake. The amounts ranged from 2 to 30 gm., and one man recovered after having drank 60 gm. When the stomach is full the chloroform is vomited and very little is absorbed. In all these cases the narcosis was complete in ten minutes, much more profound than from inhalation of chloroform. Three small children drank a chloroform liniment prescribed for their father and two died. Frank warns against ordering chloroform for external application on account of the possibility of accidents from this source. He also urges the substitution of other equally effective substances for internal use when prescribing for heedless patients. Aqua chloroformii for rinsing the stomach should be prepared by the apothecary, and should never be used where there is a suspicion of an idiosyncrasy to chloroform. He cites several cases in which serious accidents were observed only to be attributed to this cause. The use of chloroform as a vermifuge has been condemned by Leichtenstein and others as ineffectual and dangerous.

**86. Microscopic Investigation of the Blood for Diagnosis of Intra-Abdominal Suppuration.**—Schnitzler summarizes the results of his researches and experience as follows: If leucocytosis is observed accompanying symptoms of ileus, it speaks against a mechanical obstruction of the intestines and proclaims the presence of peritonitis or appendicitis. If there

are symptoms of ileus and no leucocytosis, the evidence is in favor of a mechanical obstruction, even if there is fever. The increased leucocytosis, if it is the only symptom of the increasing suppuration, might possibly serve as an indication for intervention without further delay, but there are usually pregnant concomitant symptoms at this stage of the process. The increase in the leucocytosis indicates the gradual increase in the suppuration, but it is impossible to schematize and set up certain figures as the absolute danger points. The general symptoms and the aspect of the patient are of greater importance for the diagnosis than the mere blood count.

**92. Experimental Study of Treatment of Fractures.**—Bassi reports the results of ten series of experiments on rabbits killed in one to thirty-six days after a bone had been fractured and treated by various methods. He found that massage and mobilization are evidently a distinct advantage in treatment of a fracture when there is no dislocation of the fragments; also for cases in which a temporary apparatus allows systematic massage.

**93. Treatment of Ileus.**—Chassel advocates evacuation of gases by puncture. The needle can be left for fifteen minutes to an hour or longer, and is a harmless and effective method of relieving and gaining time. The hole is invariably closed by the mucus as the fine needle is withdrawn as he has established on the cadaver and also in the clinic. There is thus no danger of the escape of fecal matter.

**100. Experimental and Clinical Experiences with Jensen's Phototherapy.**—Velyaminoff reports successful curative results in 38 cases of ordinary lupus, 19 of the erythematous variety, 10 of rodent ulcer and 10 of telangiectasia. The experimental and clinical research undertaken at the same time confirmed the destructive influence of the light, applied in this way, on the lower organisms and also on certain cellular elements of the tissues, such as giant cells and the lymphoid cells in lupus. On the other hand, he established the fact that the light has a distinct action in promoting the formation of cicatricial tissue. The combination of these two actions explains the clinical benefit derived.

**104. Forward Luxation of the Humerus and Tearing Off of the Greater Tuberosity.**—This complication is not so rare as generally supposed, Turner preclaims, and the possibility of it should not be forgotten in examining the arm in such a case.

**109. Treatment of Tetanus by Instillation of Serum in Spinal Canal.**—Jacob reports two cases and states that this procedure has been followed by success in two-thirds of all the cases thus treated at the Charité. About 5 or 10 c.c. of cerebrospinal fluid are withdrawn and then 10 to 20 c.c. of antitoxin are injected very slowly, under weak pressure.

**116. Treatment of Tuberculosis.**—Garcera applies antiseptic substances directly to the lungs by means of electric discharges which carry the antiseptic to the affected points. This procedure is supplemented by inhalation of antiseptic gases and local application of medicated sprays over the lesion, alternated with the interrupted current. He claims to have cured 70 per cent. of his patients in the first and second stages by this method. This preliminary communication is merely for the purpose of establishing priority.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**A PRACTICAL MANUAL OF INSANITY.** For the Student and General Practitioner. By Daniel R. Brower, A.M., M.D., LL.D., Professor of Nervous and Mental Diseases in Rush Medical College, in Affiliation with the University of Chicago, and in the Post-Graduate Medical School, Chicago; and Henry M. Bannister, A.M., M.D., formerly Senior Assistant Physician, Illinois Eastern Hospital for the Insane. Cloth. Price, \$3.00 net. Handsome octavo of 426 pages, with a large number of full-page inserts. Philadelphia and London: W. B. Saunders & Co. 1902.

**PROGRESSIVE MEDICINE, VOL. I, 1902.** A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surg.

ical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Octavo, handsomely bound in cloth, 452 pages, 5 illustrations. Per volume \$2.50, by express prepaid to any address. Per annum, in four cloth-bound volumes, \$10. Philadelphia and New York: Lea Brothers & Co.

THE ROENTGEN RAYS IN MEDICAL WORK. By David Walsh, M.D. Edin., Physician Western Skin Hospital, London, W. Part I—Apparatus and Methods, Rewritten by Lewis Jones, M.D. Cantab., F.R.C.P., Medical Officer in Charge of Electrical Department of St. Bartholomew's Hospital. Part II—Medical and Surgical. Third Edition. Cloth. Pp. 316. Price, \$2.50. New York: Wm. Wood & Co. 1902.

MORPHINISM AND NARCOMANIA from Opium, Cocain, Ether, Chloral, Chloroform, and other Narcotic Drugs; also the Etiology, Treatment, and Medicolegal Relations. By T. D. Crothers, M.D., Superintendent of Walnut Lodge Hospital, Conn. Handsome 12mo of 351 pages. Cloth. Price, \$2.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

JOHNSON'S FIRST AID MANUAL. Suggestions for Prompt Aid to the Injured in Accidents and Emergencies. Edited by Fred B. Kilmer. Illustrated. Pp. 113. Cloth. Price, 50 cents. New Brunswick, N. J.: Johnson & Johnson. 1901.

FIFTH ANNUAL REPORT OF THE STATE INSTITUTION FOR FEEBLE-MINDED OF WESTERN PENNSYLVANIA. Polk, Venango County, for the Year Ending Sept. 30, 1901. Paper. Pp. 34. Oil City, Pa.: Derrick Pub. Co. 1901.

THE INTERNATIONAL MEDICAL ANNUAL: A Year-Book of Treatment, and Practitioner's Index. 1902. Twentieth Year. Cloth. Pp. 688. Price, \$3.00. New York: E. B. Treat & Co.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., March 20 to 26, 1902, inclusive:

Edward C. Carter, major and surgeon, U. S. A., leave of absence extended one month.

Jerre B. Clayton, lieutenant and asst.-surgeon, U. S. A., member of a board at Fort Myer, Va., to examine officers of the Army for promotion.

Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., retired from active service on account of disability.

William R. Davis, major and surgeon, U. S. A., member of a board at Fort Myer, Va., to examine officers of the Army for promotion.

Willis S. Horne, contract surgeon, now at Fort Sheridan, Ill., relieved from further duty in the Division of the Philippines, and to proceed to his home, Marlin, Tex., for annulment of contract.

James P. Kimball, colonel, asst. surgeon-general, U. S. A., to report for examination by the retiring board in session at Governor's Island, N. Y.

Frank E. McDermott, contract dental surgeon, former orders directing him to proceed to Fort Crook, Neb., for duty revoked, but this revocation was cancelled by a subsequent order.

George Newlove, contract surgeon, leave of absence for two months granted.

George F. Owens, contract surgeon, to proceed from Washington, D. C., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Martin A. Probert, contract surgeon, now at Columbus Barracks, Ohio, is relieved from further duty in the Division of the Philippines and assigned to duty at Fort Crook, Neb.

William W. Quinton, captain and asst.-surgeon, U. S. A., leave of absence for one month granted.

Robert P. Robins, major and surgeon, Vols., leave of absence from the Department of California extended one month.

Louis A. Spaeth, contract surgeon, now at Fort Sheridan, Ill., is relieved from further duty in the Division of the Philippines and will proceed to Jersey City, N. J., for annulment of contract.

Louis A. Thompson, contract surgeon, leave of absence on account of sickness extended two months.

Gideon McD. Van Poole, lieutenant and asst.-surgeon, U. S. A., now at the General Hospital, Presidio of San Francisco, Cal., to report at the Army and Navy General Hospital, Hot Springs, Ark., for treatment.

### Appointments, Promotions, Retirements, Etc.,

recorded in the Adjutant-General's Office between Feb. 15 and March 15, 1902:

**Regular Army, Promotions.**—Feb. 14, 1902: Lieut.-Col. Robert M. O'Reilly, deputy surgeon-general, to be assistant surgeon-general with the rank of colonel; Major Edward B. Mosley, surgeon, to be deputy surgeon-general with the rank of lieutenant-colonel; Capt. Benjamin L. Ten Eyck, asst.-surgeon, to be surgeon with the rank of major.

**Volunteers, Appointments.**—To be surgeon, with the rank of major: Capt. Roger P. Ames, asst.-surgeon, Vols., Jan. 6, 1902. To be asst.-surgeons, with the rank of captain: Edward A. Romig, of Michigan, Feb. 5, 1902, and William J. S. Stewart, of Massachusetts, contract surgeon, Feb. 4, 1902.

**Honorably Discharged.**—The following captains, asst.-surgeons: Charles Anderson, February 16; Allen D. McLean, February 17; Jerome B. Thomas, February 27; Carl R. Hexamer, February 28; Wharton B. McLaughlin, March 10, and Joseph J. Curry, March 14, 1902.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ending March 29, 1902:

Surgeon W. R. Du Bose, ordered to report on the Wisconsin to the Commander-in-Chief of the Pacific Station as fleet surgeon.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers for the U. S. Marine-Hospital Service for the seven days ended March 27, 1902:

Surgeon J. H. White, to proceed to Baltimore, Md., for special temporary duty.

Surgeon P. M. Carrington, to proceed to Fort Bayard, East Las Vegas and Santa Fe, New Mexico, for special temporary duty.

P. A. Surgeon H. D. Geddings to proceed to Baltimore, Md., for special temporary duty.

P. A. Surgeon J. B. Greene, granted leave of absence for seven days from March 18, 1902, under Paragraph 181 of the regulations.

A. A. Surgeon F. B. Adams, granted leave of absence for twenty days from April 1.

A. A. Surgeon B. Kinsell, granted leave of absence for ten days from February 10.

A. A. Surgeon F. Townsend, granted leave of absence for one month from March 15.

A. A. Surgeon W. O. Wetmore, leave of absence for fourteen days, granted by previous order, revoked.

#### BOARD CONVENED.

Board convened to meet at the Bureau March 24, 1902, for the physical examination of candidates for admission to the Engineer Corps, R. C. S. Detail for the Board: P. A. Surgeon H. D. Geddings, chairman; Asst.-Surgeon B. S. Warren, recorder.

#### APPOINTMENT.

W. E. Rice, of Maine, appointed acting asst.-surgeon for duty at Bath, Maine.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended March 29, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, March 8-15, 6 cases; Sacramento, March 8-15, 1 case; San Francisco, March 8-16, 13 cases.

Colorado: Denver, March 8-15, 8 cases.

Illinois: Belleville, March 15-22, 2 cases; Joliet, March 1-15, 8 cases.

Indiana: Evansville, March 15-22, 5 cases; Indianapolis, March 15-22, 14 cases.

Iowa: Clinton, March 15-22, 1 case.

Kansas: Wichita, March 15-22, 5 cases.

Kentucky: Covington, March 16-23, 8 cases.

Maine: Portland, March 15-22, 4 cases.

Massachusetts: March 15-22, Boston, 19 cases, 2 deaths; Cambridge, 5 cases, 1 death; Fitchburg, 3 cases; Lawrence, 4 cases; Malden, 2 cases; Somerville, 2 cases.

Michigan: Detroit, March 15-22, 13 cases; Grand Rapids, March 8-22, 4 cases; Ludington, March 15-22, 19 cases.

Nebraska: Omaha, March 15-22, 29 cases.

New Jersey: Elizabeth, Dec. 28-March 15, 13 cases, 1 death; Hudson County, March 9-16, 48 cases; Jersey City, March 9-23, 78 cases, 1 death; Newark, March 15-22, 25 cases, 5 deaths.

New York: Binghamton, March 15-22, 1 case; New York, March 15-22, 66 cases, 13 deaths; Yonkers, March 14-21, 2 cases.

Ohio: Cincinnati, March 14-21, 25 cases.

Pennsylvania: Allegheny City, March 15-22, 1 case; Philadelphia, March 15-22, 35 cases, 3 deaths; Pittsburg, March 15-22, 4 cases.

Rhode Island: Providence, March 15-22, 5 cases.

South Carolina: Greenville, March 8-15, 7 cases.

South Dakota: Sioux Falls, March 15-22, 4 cases.

Tennessee: Memphis, March 15-22, 13 cases.

Washington: Tacoma, March 8-15, 10 cases.

West Virginia: Wheeling, March 15-22, 2 cases.

Wisconsin: March 15-22, Green Bay, 23 cases, 1 death; Milwaukee, 3 cases.

#### SMALLPOX—FOREIGN.

Belgium: Antwerp, March 1-8, 18 cases, 3 deaths.

Canada: Halifax, March 15-22, 9 cases; Hamilton, March 15-22, 1 case; Quebec, March 15-22, 22 cases; Winnipeg, March 1-15, 9 cases.

China: Hongkong, Feb. 1-8, 1 case.

Colombia: Cartagena, March 3-9, 1 death; Panama, March 10-18, 50 cases.

France: Paris, March 1-8, 3 deaths.

Great Britain: England—Leeds, March 8-15, 2 cases; London, March 1-8, 553 cases, 80 deaths; North Shields, Feb. 22-March 8, 16 cases, 2 deaths; Swansea, Feb. 22-March 1, 1 case; Tottenham, Feb. 22-March 1, 1 case; West Ham, Feb. 22-March 1, 7 cases.

Scotland—Dundee, March 1-8, 1 case; Glasgow, March 7-14, 95 cases, 2 deaths; Leith, March 1-8, 1 case.

India: Bombay, Feb. 18-25, 8 deaths; Calcutta, Feb. 15-22, 8 deaths; Karachi, Feb. 2-23, 14 cases, 5 deaths; Madras, Feb. 8-14, 5 deaths.

Italy: Naples, Feb. 22-March 1, 9 cases, 1 death; Palermo, Feb. 22-March 8, 27 cases, 5 deaths; Rome, Jan. 18-25, 1 death.

Russia: Odessa, March 1-8, 2 cases, 1 death; St. Petersburg, Feb. 22-March 1, 11 cases, 8 deaths; Warsaw, Feb. 15-22, 2 deaths.

Spain: Barcelona, March 8-15, 5 deaths.

Straits Settlements: Singapore, Jan. 18-25, 2 deaths.

#### SMALLPOX—INSULAR.

Porto Rico: San Juan, Feb. 22-March 1, 14 cases.

#### YELLOW FEVER.

Mexico: Vera Cruz, March 8-15, 4 cases, 2 deaths.

#### CHOLERA—FOREIGN AND INSULAR.

Philippines: Manila, March 24, 18 cases.

China: Canton, March 17, 2 deaths; Fatsan, March 19, raging.

India: Bombay, Feb. 18-25, 5 deaths; Calcutta, Feb. 15-22, 84 deaths; Madras, Feb. 8-14, 10 deaths.

Straits Settlements: Singapore, Jan. 18-25, 21 deaths.

#### PLAGUE.

Australia: New Castle, March 21, present.

India: Bombay, Feb. 18-25, 701 deaths; Calcutta, Feb. 15-22, 176 deaths; Karachi, Feb. 2-9, 53 cases, 45 deaths; Karachi, Feb. 16-23, 52 cases, 48 deaths.

### THE ETIOLOGY AND SPREAD OF TYPHOID FEVER.\*

VICTOR C. VAUGHAN, M.D.  
ANN ARBOR, MICH.

#### THE TYPHOID BACILLUS.

Is typhoid fever due to a specific, well-defined, easily differentiated micro-organism, or are there several varieties of this germ, differing from one another in cultural, tinctorial, and possibly other properties? For many years after the discovery of the Eberth bacillus bacteriologists generally held that the micro-organism causing typhoid fever constitutes a distinct, easily recognizable species. In this country, at least, the writer stood almost or quite alone in claiming that there are varieties of this germ. In 1892 in a paper read before the Association of American Physicians, and published in the transactions of that Society, I made the following statement: "It probably makes but little difference whether we conclude that these germs are varieties of one species or that they are related species. I know of no hard and fast lines upon which one can decide, to the satisfaction of everyone else, whether two or more germs differing more or less should be classified as species or as varieties. Of one thing I am certain, and that is that I am ignorant of any crucial test or of any combinations of tests upon the strength of which I can say at present that a germ which I may find in drinking water is identical with the so-called typhoid bacillus. I have found in spleens, after death from typhoid fever, germs which differ from the typhoid bacillus obtained from Berlin, and from one another as my bacillus *venenosus* differs from either or from both."

With the discovery of Gruber and Durham of the phenomenon of agglutination and with its application by Widal to the study of typhoid fever, it was at first believed that this reaction proved beyond all controversy the specific character of Eberth's bacillus; but recently Sternberg<sup>1</sup> has reported the finding in water of colon germs which agglutinate with typhoid serum in the proportion of 1-10,000, and Stern<sup>2</sup> found that in some cases of typhoid fever the blood serum agglutinates colon bacilli in a higher dilution than that in which it acts on the typhoid bacillus. It has been claimed by some that such observations as these can be accounted for by the typhoid patient suffering from a secondary infection with the colon bacillus, but Jatta<sup>3</sup> has shown that in some instances at least blood serum obtained from animals inoculated with pure cultures of the typhoid bacil-

lus has a more markedly agglutinating effect upon the colon than it has upon the Eberth germ. Gruber and Durham in their original communication on the phenomenon of agglutination reported that typhoid serum experimentally obtained in animals even in high dilutions may agglutinate the bacillus enteritidis of Gaertner. It will be seen from this (and additional evidence might be furnished if desired) that the agglutination test has failed to establish the specific character of the Eberth germ.

From time to time atypical forms of the Eberth bacillus, differing from the standard sufficiently to be classed as varieties, have been obtained from persons dead or sick with typhoid fever. Babes<sup>4</sup> was probably the first to report on these atypical forms, all of which were obtained from the organs of typhoid cadavers; but three of the varieties, or very similar bacteria, were also found elsewhere. It is undoubtedly true that the typhoid bacillus when growing outside the body, as for instance in drinking water, departs more or less markedly from the type of this germ as found in the spleen and mesenteric glands after death. Gwyn<sup>5</sup> obtained from the blood of a typhoid patient during life a germ which differed from the typical typhoid bacillus inasmuch as the former produced gas in nutritive media containing glucose. The blood serum from this patient agglutinated this germ in dilutions of 1-200 and was without action upon the typical typhoid bacillus. Schotmuller<sup>6</sup> obtained from the blood of five cases of typhoid fever, in an examination of 68 cases, bacteria which on account of their cultural properties this investigator classifies as intermediate between the colon and the typhoid germ. To sum up this part of our subject, we may say that there are bacteria which are frequently found in drinking water, more rarely in the bodies of persons sick or dead with typhoid fever, which on account of certain cultural manifestations we can not classify with either the typical colon or the typical typhoid bacilli. These intermediate forms have been designated by different names. Generally in the examination of drinking water we call them typhoid-like bacilli. In my report upon the examination of drinking water in relation to typhoid fever published in the transactions of the Association of American Physicians, in 1892, I studied these germs under the general name of *bacillus venenosus aquatilis*, or the poisonous bacillus of water, and in the paper referred to I described four varieties. By others, they have been designated as paracolon or paratyphoid groups, and some have proposed that they be designated as the Gaertner group on account of the fact that the bacillus enteritidis belongs to it. Aided by my assistants I have carried out since the first of January, 1888, a systematic study of all toxicogenic germs found in the samples of

\* An Address at the Semi-Centennial Meeting of the Chicago Medical Society, April 9, 1902.

drinking water sent to the hygienic laboratory of the University of Michigan for examination. During this time we have made careful studies of between four and five hundred samples of water which have been suspected of causing typhoid fever. These studies have led me to the following conclusions:

1. A water containing a typical colon bacillus, one which coagulates milk within from 24 to 48 hours, readily reddens litmus and produces an abundance of gas in glucose media, does not cause typhoid fever. There are several smaller cities in Michigan which send to us monthly their drinking water supply for bacteriological examination, and some of these waters contain the colon bacillus constantly; in fact, this germ never fails to appear when a test is made, and yet there have been no epidemics of typhoid fever among the people drinking these waters.

2. The more markedly a germ found in drinking water differs from the typical colon bacillus, and the more closely it approaches the typical typhoid germ, the more likely is typhoid fever to appear among those using the water containing this germ. I am not ready even after fourteen years of investigation of this matter to lay down any rules by means of which I can say just where the line should be drawn between the colon and the typhoid groups, and I still continue to speak of typhoid-like bacilli, and I have no hesitancy in condemning waters which contain these micro-organisms.

3. I have never found in any sample of drinking water a typical Eberth bacillus. I do not say that such a germ may not be found in water, but I do not believe that the typhoid bacillus preserves its typical characteristics for any great length of time when growing in water. As confirmatory to this last statement, it may be worth while to mention the fact that Remy<sup>7</sup> has found that when the typhoid bacillus is grown in company with the colon germ the former is so far changed that it can not be identified by any means at our command at present, and that it even loses its susceptibility to the agglutinating action of typhoid serum.

When asked whether or not I believe in the specific nature of the Eberth bacillus I have no hesitation in replying in the affirmative. Notwithstanding our inability in many instances to say positively whether a given micro-organism should be classed with the typhoid or the colon bacilli, I am thoroughly convinced that there is really a sharp line of demarcation between the two, and that one does not develop or emerge from the other. I do not believe that typhoid fever ever comes from the colon germ, and I am thoroughly convinced that although the typhoid bacillus may lose many of its characteristics, it is never converted into a colon bacillus. I know of too many people, whole cities full, who are drinking every day millions of colon bacilli without developing typhoid fever to permit me to believe that this germ can cause this disease. When I began my work in the bacteriological examination of drinking water fourteen years ago I condemned for drinking purposes every water which contained the colon bacillus, but an experience of six years convinced me that this opinion was wrong and since 1894 I have not condemned waters which did not contain typhoid bacilli or typhoid-like bacilli, and I have known of no epidemic of typhoid fever arising from the consumption of such waters. On the other hand, I do condemn all waters containing atypical typhoid bacilli. I hope at some time in the near future to be able to make a close study of the toxicogenic germs which have been isolated from drink-

ing waters in my laboratory, and cultures of most of which have been preserved. In fact, one of my assistants is now engaged in a comparative study of these micro-organisms.

The natural distribution of the typhoid bacillus is another subject needing careful investigation. Apparently trustworthy bacteriologists have reported the finding of this organism in the most unexpected places. Its presence has been detected in the soil of localities far removed from the habitation of man, and its isolation from drinking water supposed to be free from contamination has been reported. It must remain for future investigations to decide upon the reliability of these reported findings and to attach to them their proper significance, should they be found to be true.

*The Elimination of the Bacillus from the Body.*—In a study of the etiology and spread of typhoid fever it is important to ascertain by what avenues the specific micro-organism leaves the body of the infected individual. The exhaled air from the lungs of the typhoid fever subject is germ free, as is probably the case in all of the infectious diseases. Therefore, there is no possibility of this disease being spread by means of the air exhaled from the lungs. However, it must be borne in mind that in the pneumonias that frequently complicate typhoid fever the Eberth bacillus is found in the diseased lungs, and may be eliminated in the matter coughed up, and disseminated through the air in the fine spray that accompanies fits of coughing. It is also possible that the typhoid bacillus may be present in the sputum in advanced cases of this disease, even when there is no lung complication.

There is no positive evidence that the perspiration from one sick with typhoid fever contains the specific bacillus of this disease. It is true that this bacterium may be found on the surface of individuals suffering from the disease, but in such cases the germ owes its presence in this locality to contamination of the skin with the stools or with the urine. The urine of persons sick with typhoid fever may contain the Eberth bacillus, and several observers have found this bacterium in this excretion. In some of these cases it seems probable that the germ causes some destructive changes in the kidney, inasmuch as its presence is accompanied by the elimination of more or less albumin in the urine. However, the bacillus may be abundant in the urine when this secretion contains no albumin, and when there is no evidence of structural disease of the kidney. Persons recovered from typhoid fever may continue for weeks to eliminate in the urine millions of the Eberth bacillus. It sometimes happens that a cystitis occurs as a sequence of typhoid fever. In at least some of these cases the inflammation of the bladder is due to infection with the typhoid bacillus, and this germ in a virulent form may for a long time remain in the bladder and render the urine a possible source of the spread of typhoid fever. Houston<sup>8</sup> has reported a case of cystitis of three years' standing due to the infection of the bladder with the bacillus of Eberth. An interesting point in connection with the report of this case is that the patient never had typhoid fever, but had nursed cases of this disease. I may say parenthetically that a case very similar to this came under my observation a short time ago, and the physician in charge called my attention to its resemblance to Houston's reported case. This patient had never had typhoid fever, but had nursed a typhoid case, and subsequently developed a cystitis. I made a most careful study of this germ, and found

that it had no resemblance whatever to the typhoid bacillus, and undoubtedly belonged to the colon group. Post-typhoidal abscesses may form in various parts of the body and may discharge the Eberth bacillus in virulent form for months or even years. It is unnecessary to add that infected material of this kind should be burned or otherwise disinfected. The necessity for this is evident whether the abscess be due to the typhoid bacillus or to other bacteria.

The most important avenue for the elimination of the typhoid bacillus from the body is through the bowel. Long before the discovery of the specific micro-organism of this disease the profession had learned that the stools of typhoid patients contained the infective agent of the disease. It had been frequently observed that epidemics of typhoid fever resulted from the drinking of water contaminated with the stools of those suffering from this disease, and the more intelligent members of the medical profession recommended thorough disinfection of the feces long before the bacillus had been discovered. The elimination of the typhoid bacillus in the stools probably begins soon after its introduction through the mouth. Indeed, it is quite certain that the individual may become the bearer and distributor of the infective agent without developing the disease himself. The specific bacterium finds its way into the small intestines, in the contents of which it multiplies rapidly, and this intestinal culture may be wholly discharged from the bowels without causing any local lesions. Furthermore, it has been shown by the report of several cases that typical typhoid fever may develop and death result without intestinal ulceration. I desire to emphasize the fact that the typhoid bacillus may grow in the intestines of an individual and pass from the same without causing typhoid fever. This is most likely to occur when many irritative saprophytic germs are taken into the alimentary canal along with a few typhoid bacilli. This is probably the true explanation of the unquestionable preventive effect of diarrheas in certain epidemics of typhoid fever. I shall return to this later. The specific germ of typhoid fever may be transported from one place to another in the intestines of a man who is immune, and when cast out in the stools may become a source of danger to others. It is most likely that in some such way as this certain epidemics which appear to originate *de novo* have their start.

The stools of individuals sick with typhoid fever constitute the most important source of the spread of this disease, and it may be stated in a general way that typhoid fever is due to the transference of some part of the feces of an infected individual to the alimentary canal of one susceptible to this infection. In exceptional cases this transference may be quite direct, as when a careless nurse soils her hands with the dejections from her typhoid fever patient and then eats her food without disinfecting her soiled fingers. However, in the great majority of instances the transference is more indirect, and the germs in the infected stool may multiply through many generations and be transported by water or otherwise through considerable distances. It is also probable that the bacilli may pass through an intermediate host, which may be man or one of the lower animals. An immune individual may visit a distant city, the water supply of which is infected with the typhoid bacillus, and this man may carry the infection to his village home where it may be deposited in his normal stool, may find its way into the local water supply, and cause an epidemic of the disease.

*Longevity of the Bacillus.*—In studying the problem of the spread of typhoid fever, it is of importance for us to know how long the specific bacillus of this disease may continue to live and be possessed of its specific properties. It is also evident that when seeking for an answer to this question we must know something of the conditions under which the life of the organism is to be perpetuated. We have already seen that in the human body the Eberth bacillus may continue to grow and reproduce its kind quite indefinitely. This is known to be the case in instances of post-typhoid cystitis and abscess. I would not have it understood that I believe that cases of typhoid fever are frequently due to infection from this source, and I have mentioned these facts simply for the purpose of showing how long an individual may retain this germ in some part of his body. It is true that there is a possibility of the infection spreading to others from the germ found in these post-typhoidal conditions, but such cases must be rare except when the urine is infected. The living germ has been found in the bodies of men dead from typhoid fever three months after death. However, the longevity of this bacillus in the dead body must vary greatly, and must be dependent upon a number of conditions which are not likely to be the same in any two cases.

So far as the spread of typhoid fever is concerned, the longevity of its bacillus after it leaves the body of the infected man is of greater importance than its possible longevity in the body. When material containing this germ is spread out in a thin layer and exposed to the direct action of the sunlight, the bacilli are soon destroyed. A cloth moistened with a culture of the Eberth bacillus and exposed to the direct sunlight soon fails to yield a growth when a bit of it is placed in a suitable culture medium. However, we must not get too much comfort out of the fact that the typhoid bacillus is killed by an exposure of a few hours to the light of the sun. Practically, typhoid stools are not spread out in thin layers or otherwise placed in a condition suitable for the light to exert a markedly germicidal action on them. It is true that the bacilli, when a small quantity of typhoid stool is smeared on a sheet, may be destroyed by a few hours' exposure to direct light, but the same material rolled in heavy blankets may retain its virulence for many weeks. Complete desiccation soon destroys the Eberth bacillus, but it may retain its vitality in relatively dry material for a long period. Bits of agar or gelatin cultures placed upon cloth, leather, wood, or metal retain the living bacillus for many months, and clothing or bedding soiled with typhoid stools may be the means of spreading this disease. The experiments of Uffelmann<sup>9</sup> show that the bacillus may retain its vitality in layers 4 mm. thick on wood for 32 days, on linen for 62 days, and on woolen cloth for 80 days.

The experiments made for the purpose of determining the longevity of this bacillus in the soil have yielded widely different results. This is explained by the fact that no two investigators have conducted their experiments under exactly the same conditions. When cultures of the Eberth bacillus are mixed with dust or pulverized earth of any kind and completely desiccated the germs speedily die, but when the desiccation is not complete, the bacilli may retain their vitality for weeks and months. Since desiccation soon destroys the germ of typhoid fever, it has been inferred that this disease can not be spread by particles of dust carried through the air, but we know that particles of dust thus carried are by no means always completely desiccated. Currents

of air may and do carry through great distances considerable particles of moist dust. Considerable interest is attached to the question of the vitality of this organism in the soil about sinks and privies containing typhoid stools. After the Franco-German war it was found that typhoid fever continued to prevail for several years in garrisons in which soldiers sick with typhoid fever had lived. An interesting case of this kind is the following: An epidemic of typhoid fever began among German soldiers located in a certain garrison on April 4, 1872. During the war these barracks had been occupied by French prisoners, among whom typhoid fever had prevailed. Large sinks had been filled with the undisinfected stools of the prisoners, and when filled, these sinks, located just outside the barracks, were covered with thin layers of earth. The water of a well near by had probably become infected from these sinks and caused the epidemic in the garrison in 1872. After the appearance of the epidemic the old sinks were cleaned out and the well thoroughly disinfected. Four days later the last case of typhoid fever occurred in this garrison. Some interesting experiments have been made in England for the purpose of determining the longevity of the typhoid bacillus in the soil. Martin took specimens of dirt from various sources, some being obtained from localities where it was known that the soil was largely contaminated with organic matter, and where typhoid fever had been epidemic, while others were obtained from places which had not been contaminated by sewage or in any other way. These samples were pulverized, placed in Erlenmeyer flasks and sterilized, after which they were inoculated with cultures of the typhoid bacillus. It was found that the Eberth germ grew luxuriantly in the polluted earth, and that flasks containing this soil showed growths of this micro-organism after the lapse of 105 days. The results were different in the case of the unpolluted earth, inasmuch as the germ not only failed to multiply, but after a short time died out.

Investigations of Klein indicate that the process of nitrification as it goes on in soil favors the growth and development of the typhoid bacillus. Klein had ascertained, as others before him had done, that sewage is not a suitable medium for the growth of this germ, but subsequently he found that by the addition of nitrates to crude sewage the latter is converted into a more suitable medium for the growth of this organism. In fact, in this modified sewage the typhoid bacillus grows abundantly. Robertson selected a grass-covered field for his investigations on the longevity of the typhoid bacillus. Patches of turf were cut and removed from the subjacent soil. In one locality the ground immediately below the turf was watered with a culture of the bacillus, after which the turf was replaced. In another, nine inches of the earth beneath the turf was removed and the Eberth bacillus sown at this depth, while in the third experiment the germ was placed at a depth of eighteen inches, the soil which had been removed being carefully replaced after depositing the germ. One hundred and thirty days after this had been done the soil under the turf of the infected localities was removed and examined. Robertson found that in all cases the bacilli had not only retained their vitality, but had multiplied. In the place where the germ had been buried eighteen inches beneath the surface it had grown through the earth above it where it was found widely and abundantly distributed. Some of these plantings were made in July, 1895, and during the cold months of the

following winter no typhoid bacilli could be obtained from the soil in which they had been deposited, but during the following spring these spots were treated with dilute sterile broth in order to furnish material for the growth of the micro-organisms and furthermore for the purpose of rendering the conditions similar to those existing in cases of pollution with sewage; and it was found on the following June, nearly a year after the time of the planting of the germ, that those localities, which had been properly fertilized with the beef broth, furnished abundant crops of the micro-organism, while areas which had not been so fertilized failed to show any growth. These experiments indicate that a polluted soil when once infected with the typhoid bacillus may retain the infection for a long time, and this finding is quite in accord with military experience, inasmuch as it has frequently been found that a healthy regiment may speedily develop this disease after occupying a site vacated by an infected command. The history of typhoid fever among the troops during the War of the Rebellion furnishes instances of this kind, one or two of which may be mentioned. The 23d Massachusetts left that State in November, 1861, and was encamped at Annapolis, Maryland, until Jan. 6, 1862, the record of health being good up to that time. On March 14, 1862, this regiment arrived at New Berne, North Carolina, with the health of the regiment still good, notwithstanding exposure to many hardships. On arriving at New Berne the regiment occupied an encampment, including tents, abandoned by a Confederate regiment that had suffered severely from typhoid fever. This disease soon broke out in the Massachusetts regiment and during the month of April, 1862, 300 cases developed and 22 deaths occurred.

On March 7, 1862, the 10th New York Cavalry moved into barracks at Perryville, Maryland, which had recently been vacated by the 14th U. S. Infantry, the latter regiment having suffered largely from typhoid fever during the month of February. On the arrival of the New York regiment the barracks were thoroughly cleaned, drains opened, and improved, and an excellent spring, supposed to be exempt from any source of pollution, was found. It should be stated that the 14th Infantry had not used water from this spring, but had taken it from a well only six feet deep. Notwithstanding the precautions taken by the New York regiment typhoid fever soon made its appearance. Other illustrations equally striking might be given from the histories of military campaigns.

It will be seen from what has already been stated that both experimental evidence obtained with pure cultures of the bacillus and epidemicological observations in the study of typhoid fever show that infected things and places may remain sources of danger for weeks and months. These facts have not been sufficiently impressed upon the medical profession, and the necessity for careful disinfection of soil, clothing, bedding, etc., has not been appreciated.

Inasmuch as epidemics of typhoid fever are frequently spread by means of drinking water, the longevity of the bacillus in this medium is of importance. Many experiments have been made for the purpose of obtaining information on this subject, but the results have been somewhat contradictory. In distilled water and sterilized drinking water obtained from springs, wells, rivers and lakes and kept at ordinary room temperature without exposure to direct sunlight, the typhoid bacilli may rapidly multiply and may retain their vitality for three

or four months. In ordinary unsterilized water the conditions that influence the life of the typhoid bacillus are many and variable. In the first place the chemical composition of the water is not without effect upon the longevity of the germ. As has already been stated, sewage ordinarily does not form a good medium for the growth of the Eberth bacillus, but as Klein has shown, the addition of nitrates renders the growth abundant, and that processes of nitrification are constantly going on in polluted water is shown by the presence of nitrates and nitrites. Evidently the kind and number of other germs present in infected water have much to do in determining the longevity of the typhoid bacillus in such mixed cultures. Some of the ordinary water bacteria undoubtedly hasten the death of the typhoid bacillus owing to the fact that the conditions of growth are more favorable to the former than to the latter, but experimental evidence on this point is not always conclusive, because the water bacteria are present in relatively much greater numbers than the typhoid bacillus, and failure to detect and isolate the latter is not always convincing proof of its absence. Westcott<sup>10</sup> reports a case of apparently great longevity of the typhoid bacillus in water. He states that he was able to trace nineteen cases of typhoid fever to a well drawing its supply from a sewage contaminated area. On closing the well the epidemic ceased, but on reopening it for the purpose of obtaining water for laundry purposes another case occurred. The well had been closed twenty weeks, and during this time the conditions were such that the introduction of further contamination was improbable.

In certain liquid foods, such as milk, bouillon and broth, the typhoid bacillus may retain its vitality for months. This is true whether the food be sterilized or unsterilized at the time of the introduction of this organism. When deposited on solid food, such as potatoes, bread, and meat, the typhoid germ may retain its vitality as long as such foods are likely to remain palatable.

#### THE DISSEMINATION OF TYPHOID FEVER.

1. *Transported by Man.*—Man himself is the most active agent in the dissemination of this disease. He may carry the specific virus in his alimentary canal, on his person, or in his clothing, and in this way the germs may be transported hundreds and thousands of miles and may be widely distributed. For instance, an infected recruit may plant the specific bacillus in every latrine in his regiment before he is suspected of having the disease himself. The history of mining expeditions also gives us instances of the transportation of typhoid fever to places far remote from the permanent habitations of man. Indeed, the history of typhoid fever justifies the statement that wherever and whenever men congregate and live without adequate provision for disposing of their excrement, there and then typhoid fever will appear. This seems to be so universally true that many men who have been engaged in the study of the epidemiology of this disease have come to agree with Murchison in his pythogenic doctrine concerning the origin of this disease. This theory supposes that typhoid fever may be generated independently of a previous case by the fermentation of fecal and other forms of organic matter. This conclusion resulted from the difficulty generally experienced in tracing the introduction of the disease, and we now know that it is erroneous. The board appointed by the Surgeon-General to study typhoid fever in the encampments of the United States in 1898, and of which the speaker was a member, and

whose report has not been published, was able to trace typhoid fever into every encampment in which it became epidemic.

2. *Dissemination through the Air.*—Is typhoid fever ever disseminated through the air? This is a question to which diverse answers have been given. Our present knowledge of the etiology of this disease gives no support to the old belief that it may be caused by the inhalation of gases from decomposing organic matter. Infection can result only from the specific germ, and no amount of decomposing matter in which this organism is not present can cause the disease. Again, the specific cause of typhoid fever is a particulate body and not a gas. Inhalation of gases from putrid material may cause intoxication, but not infection so long as these gases are free from micro-organisms. Many cases reported by older writers in which typhoid fever was believed to be due to the inhalation of gases from putrid matter were, as we can now see, not instances of infection. As an illustration of this we may mention the Clapham epidemic, reported by Murchison, and frequently quoted. Out of 22 school boys who watched the opening of a pit containing a large amount of decomposing matter, and which had been closed for some years, 20 were within three hours prostrated with vomiting and diarrhea. Two died, one within twenty-three and the other within twenty-five hours. Postmortem examination showed acute swelling of Peyer's patches and the solitary follicles, with slight ulceration of these structures, together with congestion of the mesenteric glands. These were diagnosed as cases of typhoid fever, but we now know that they were instances of acute poisoning with noxious gases. The oldest cultures of the typhoid bacillus are free from disagreeable smells, and infection is not likely to result from ingestion of putrid material. I wish to emphasize the difference between the question now before us, as to whether or not typhoid fever may be disseminated by infected particles of dust carried through the air, and the older idea, that it was spread by the agency of gases given off from putrid material. Such gases are generally germ free. On the other hand, a wind may carry partially dried infected particles of dust, which may be deposited on food or inhaled and cause typhoid fever. However, I am reaching a conclusion before giving the arguments. Germano,<sup>11</sup> after reviewing the literature of this subject, endeavored to decide the question concerning the possible dissemination of typhoid bacilli through the air experimentally. In his investigations Germano found that typhoid bacilli mixed with dust from different sources and thoroughly desiccated speedily die, and he concluded that air infection through many hundred meters is impossible. In my opinion Germano's investigations confirm what was already well known, that the typhoid bacillus is speedily deprived of life by desiccation, but they do not convince me that dissemination of the living germ in particles of partially dried dust or bits of infected fecal matter may not be carried even through distances of many hundred meters and deposited upon the food, in the drinking water, or inhaled. Neisser<sup>12</sup> has shown that dust infected with the typhoid bacillus may be carried by a current of air moving at the rate of 1.7 cm. per second through a distance of 60 cm., and there deposited with the germs still possessed of vitality. However, he concludes that since the germ is not transported to a distance of more than 60 cm. by the air moving at the rate which generally prevails within a room, that typhoid fever can not be considered

a dust disease. It will be seen that this conclusion has reference only to the possibility of the typhoid bacillus floating through the air of a closed room, but even within doors the air often moves with a velocity many times greater than 1.7 cm. per second. Especially is this true when the movement of air within a room is influenced by draughts from windows, doors and ventilating flues. Partially dried typhoid stools on the floor may be sufficiently comminuted to form an infected dust which may float through the air, be deposited on food, find its way into uncovered receptacles of water or milk, or be directly inhaled and find lodgment in the nose and pharynx, and finally reach the intestines. The danger of air infection is greatly increased in military life where food and drink are often exposed for hours to an atmosphere laden with dust and possibly infected with the typhoid bacillus. At Chickamauga in 1898 the surface of the ground about many of the regimental encampments was so covered with fecal matter that it was impossible to walk through these places without soiling the feet. So prevalent was typhoid fever that much of this fecal matter must have contained the Eberth bacillus, and it seems hardly possible that the great clouds of dust in which the men lived could have been free from this infection. The shell roads through the encampments at Jacksonville were ground by the heavy army wagons into an impalpable dust many inches thick. Along these roads scavengers carted in half barrels fecal matter generally infected, and the contents of these tubs often splashed over and fell into the dust. On each side of these roads soldiers were encamped, and many mess tables were in close proximity. Local whirlwinds sometimes caught up large quantities of dust and carried it considerable distances. After seeing these things I am of the opinion that we can not exclude dust as a probable carrier of the typhoid infection, notwithstanding the fact that it would probably prove a very difficult thing to scientifically demonstrate that the disease was disseminated in this way.

3. *Influence of the Soil.*—There is an old theory concerning the relation of the soil to the causation of typhoid fever which still has many advocates. This theory supposes that decomposing organic matter in the soil passes through a ripening process by means of which the typhoid poison is either generated *de novo* or is greatly increased in virulence. Reference has already been made to the pythogenic theory of Murchison, and this in a more or less modified form has been accepted and is advocated by many prominent epidemiologists, especially those with military experience. It is believed that different soils vary in their adaptability to harbor, grow and ripen this poison. The believers in the pythogenic doctrine may be divided into two groups: 1. those who hold that soil contaminated with any fecal matter will generate the poison; 2. those who believe that the introduction of the specific bacillus is necessary, but that this undergoes a ripening process in the soil by means of which its virulence is greatly augmented. Scientific support of the theory of the ripening of the typhoid poison in the soil has been found in the investigations of the late Professor Pettenkofer into the etiology of typhoid fever in Munich. During the first half of the last century typhoid fever was continuously endemic in that city. Munich is situated on a bed of gravel and marl, and during the time mentioned fecal matter was deposited in pits and allowed to percolate into the soil from which the drinking water, collected in shallow wells and surface springs, was taken. With

our present knowledge of the etiology of this disease we would suppose that with the above-mentioned conditions the drinking water was specifically contaminated. However, Pettenkofer, from his very careful studies of the distribution of the disease, came to the conclusion that its prevalence was not due to contaminated water. After many years of careful and skilful investigation he found that the prevalence of typhoid fever varied inversely with the height of the ground water below the surface. The nearer the ground water came to the surface, the less typhoid fever. With the fall of the level of the ground water the number of cases increased. He concluded from this that the deeper layers of the soil contained putrefactive material in which the typhoid poison undergoes a ripening process, and that the ripened germ passes from the soil into the air and is inhaled by susceptible persons. When the level of the ground water is high, the putrefactive material in which the ripening is supposed to be going on is covered by the water, and its escape into the air is prevented, while a fall in the ground water leaves the putrefying substances uncovered, and the poison is exhaled from the soil. Pettenkofer believed that the specific poison must be present, but that this undergoes in the soil changes by means of which its virulence is augmented. If this theory be true it should hold good for other cities as well as for Munich, and numerous other investigators have found that elsewhere this supposed relation between ground water and the prevalence of typhoid fever is by no means constant. Indeed, there are so many exceptions to Pettenkofer's rule that his theory must be abandoned as an explanation of the origin of epidemics of typhoid fever. There is no reason for believing that in the ordinary movements of the air from the pores in the ground to the atmosphere the velocity is sufficient to carry dust laden with bacilli. Certainly such a transference of the bacillus from the deeper layers of the soil to the atmosphere in the form of dust must be of most exceptional occurrence if it ever happens. It is proper to state in this connection that some epidemiologists accept that part of Pettenkofer's theory which provides for the ripening of the poison in the soil, but believe that the ripened and highly virulent bacillus finds its way into drinking water.

4. *Dissemination through Drinking Water.*—There can be but little doubt that in civil life the great epidemics are caused by the specific infection of drinking water. The danger in drinking water was recognized long before the discovery of the specific bacillus, and indeed epidemics had been unquestionably traced to contaminated water supply. The most frequent contamination of water with typhoid material results from the introduction into the water of the feces or urine of some infected person. After this has happened the rapid multiplication of the organism in water permits the speedy infection of a large volume. Moreover, in flowing streams the specific bacillus may be carried long distances. Variations in the temperature of this medium do not apparently affect the virulence of the germ. It may be frozen in ice and remain in this condition quite indefinitely without any loss in potency, and it is equally unaffected by alternate freezing and thawing. The fact that typhoid fever is frequently disseminated through drinking water is so well known that I will not take up any space in giving instances.

5. *Transportation on the Person, or in Clothing.*—That the infection of typhoid fever is often carried on the hands or in the clothing of nurses or other attend-

ants, there can scarcely be any doubt. This is probably one of the most frequent means by which the disease is spread through a family after its introduction. The mother, or other attendant on the sick, handles the food of the well without disinfection of the hands. Superficial ablution with soap and water is not sufficient to destroy the vitality of this organism. Thorough disinfection with special attention to the material collected under the finger nails is absolutely essential. At one of the division hospitals at Camp Alger in August, 1898, the members of our board observed the nurses, many of whom went directly from their duties in the typhoid wards to their mess tents, handle the food eaten by themselves, and pass articles to their neighbors without even washing their hands. Another practice in the army was undoubtedly accountable to a greater or less extent for the spread of typhoid fever among the soldiers in the various encampments in 1898. It was customary in several of the camps to take a fresh detail of men from the line each day as orderlies in the hospital. These men, at least the majority of them, were wholly ignorant of the nature of infection; they had never had any training as nurses; they knew nothing of the desirability or necessity of being careful in order to prevent infecting themselves, and they knew less about means of disinfecting their hands soiled with typhoid discharges. At the close of the day these men were returned to their company tents and the next morning a new detail of the same number went through the same routine. More effective means for the spread of typhoid fever could scarcely have been devised. Many of the so-called cases of prolonged incubation after exposure to typhoid fever can be best explained by the supposition that the infected material is carried on the person for some time before it finds its way into the alimentary canal. Experimental evidence shows that pure cultures of the typhoid fever bacillus will retain their virulence when poured upon cotton, linen, or woollen cloth for from two to three months, and it is altogether possible that the infection may be carried in a blanket roll for a much longer time. The personal and bed linen of patients sick with typhoid fever when soiled with discharges from the kidneys or bowels should be immediately immersed in a properly prepared disinfecting solution. When such articles are thrown aside without previous disinfection flies may carry the infection from the stains to articles of food, and moreover, after the material dries, handling these articles may scatter the infected material through the air in the form of fine dust.

6. *Dissemination by Flies.*—Our board in investigating the etiology and spread of typhoid fever in 1898 gave the following reasons for coming to the conclusion that flies were the most active agents in the spread of typhoid fever among our soldiers:

1. The latrines contained fecal matter specifically infected with the typhoid bacillus.

2. Flies alternately visited and fed upon this infected fecal matter and the food in the mess tents. More than once it happened when lime had been scattered over the fecal matter in the pits, flies with their feet covered with lime were seen walking over the food.

3. Typhoid fever was much less frequent among members of messes who had their mess tents screened than it was among those who took no such precaution.

4. Typhoid fever gradually died out in the fall of 1898 in the encampments at Knoxville and Meade, with the disappearance of the fly, and this occurred at a time

of the year when in civil practice this disease is generally on the increase.

#### CONDITIONS INFLUENCING THE SPREAD OF THE DISEASE.

*Influence of Season.*—The prevalence of typhoid fever is apparently influenced largely by season. This certainly is true in the north temperate zone in Europe and in America. The disease is most prevalent during late summer and fall, and is less prevalent during the spring months. As a rule, the increase in frequency begins to be observable in July and continues according to the season and local conditions to increase until the last of October or November. In December, as a rule, the decrease in frequency is noticeable and continues until the minimum is reached in March, April and May. The researches of Flint, Wood and others showed this to be true in the United States soon after the medical profession learned to distinguish between typhus and typhoid fevers, and more recent authorities in this country have confirmed this observation. Curschmann, Fiedler and others find the same to be true in Germany, and Murchison in his classical studies of typhoid fever showed that season has a like effect on the prevalence of this disease in Great Britain.

While it is probably generally true that typhoid fever is most prevalent in the fall, great epidemics of this disease do not always occur at this season of the year. In fact, the greater prevalence of typhoid fever in the fall of the year is not so marked now as it was thirty years ago, because of the altered conditions under which we live. This relationship of typhoid fever to season has always been more evident in a rural than in an urban population. At present the most striking epidemics of typhoid fever are those that occur in cities and are due to an infected water supply. Season affects these epidemics to the extent to which it modifies the chances of water infection. Many such epidemics within recent years have occurred in the spring of the year during the months in which, according to the general rule, the prevalence of typhoid fever should be at a minimum. Water infection is likely to occur when the snow melts and the ice breaks up, and infected material deposited on the snow or ice during the winter finds its way into the water supply. Epidemics of typhoid fever due to infected water supply are quite independent of season except as stated above. On the other hand, epidemics due to insects and those caused by the dissemination of the germ in the form of dust are more likely to occur during late summer and autumn. The same is probably true of some epidemics in rural places due to infected wells. Contaminated material is more widely and easily disseminated in summer and fall than during other seasons of the year. In the summer time or in the early fall a typhoid stool thrown on the surface of the ground may be scattered far and wide by the wind, may be carried on the feet of men or animals, may be washed into wells or springs, and in short its wide dissemination is more likely to occur at this season of the year than at any other. These facts, in my opinion, sufficiently explain the relation of typhoid fever and season, so far as such a relation exists.

*Influence of Age.*—That typhoid fever is more likely to occur in persons of certain age than in others younger or older is shown by voluminous statistical evidence. However, we must not be too hasty in arriving at conclusions on this point. First, I will make some general statements and will then briefly discuss the same. Curschmann states: "Undoubtedly early adult life especially predisposes the individual to typhoid fever.

Individuals from 15 to 35 years of age are in greatest danger of this disease. In my experience at least four-fifths of all cases have occurred among people within these limits, and more than half (about 56 per cent.) have been between 15 and 25 years of age. Between 30 and 35 years the percentage begins to fall, and from 35 to 40 it sinks rapidly. After the 50th year the percentage or morbidity of this disease falls to a fraction. In old age typhoid fever is seldom seen. During the first year of life, as is the case with most infectious diseases, typhoid fever is rare. From the 1st to the 5th year morbidity from this disease increases. From the 5th to the 15th year the disposition to typhoid fever is increased, and is greater than it is during the period from 35 to 40 years."

Murchison reported 52 per cent. of his cases among individuals from 15 to 25 years of age. Fiedler found 58.8 per cent. of his cases to range from 20 to 30 years of age, while only 3.4 per cent. were over 40, and 0.7 per cent. over 50.

This apparent predisposition of early manhood to typhoid fever may be at least partially explained. In the first place it is at this time of life that man is most inclined to roam about, obtaining his water and food from the most diverse sources, and it must be evident that his chances of infection are greater than either earlier or later in life. In the second place it is probable that many of those who have reached 40 years of age have acquired a certain immunity to the disease without ever having developed it in recognizable form. I shall give some evidence later tending to show that short diarrheas often give at least temporary immunity to this disease. How long this immunity may last in different individuals we have no means of positively determining. The infant, taking its nourishment exclusively from its mother's breast, has but little opportunity of being infected with typhoid fever. As the child grows up and seeks its food and drink from other sources danger of typhoid fever infection increases in direct proportion to the diversity of the sources from which he draws his supply. During the period of life when he mingles most largely and most promiscuously with other men, the danger of infection is increased. Later in life he becomes tethered by his habits; he visits fewer places, cares less for the society of strangers, and the chances of infection are decreased. While sickness from typhoid fever is much more frequent in early manhood, the percentage of death among cases is much greater late in life. In general, other things being equal, the percentage of mortality increases with advancing years, and ranges from 2 per cent. in early childhood to more than 50 per cent. in old age. The mortality in persons from 15 to 35 years of age averages 7.5 per cent., but of course varies considerably in different outbreaks and is modified by the individual condition of patients.

*Influence of Sex.*—Hospital statistics taken alone indicate that typhoid fever is more prevalent among men than women. However, this is not true and the apparent greater prevalence among men as shown by hospital figures is due to the fact that more men than women are treated in hospitals. Moreover, all hospital statistics do not show a greater percentage of cases among men. In London from 1848 to 1861, according to Murchison, 2431 cases of typhoid fever were treated in the fever hospital. Of these 1211 were males and 1221 were females. There is not the slightest reason for believing that sex has any influence upon susceptibility to typhoid fever. It is probably true that on the

whole a larger number of men than women have the disease, but this is due to the fact that men are more frequently exposed to infection. They travel about more. They take their food and drink from more diverse sources, and consequently the chances of infection are greater.

Pregnancy and the puerperal state apparently give some degree of temporary immunity to typhoid fever, or at least diminishes susceptibility to this disease. On this point Curschmann makes the following statement: "Greissenger finds typhoid fever to be very rare in the puerperal state and believes that nursing mothers are especially protected against this disease. In this he agrees with Rokitansky, and I myself have only seen typhoid fever appear twice in women in the puerperal state and very seldom during lactation." Pregnancy is also supposed to lessen susceptibility to this disease, but the probabilities are that the relatively small number of cases observed among women during pregnancy and the puerperal condition is due to the fact that during these times women are less exposed to infection.

*Influence of Fatigue.*—Bodily fatigue and mental worry apparently increases susceptibility to typhoid fever. The effect of fatigue is especially observable in armies. However, there are certain points connected with the study of this subject that are not altogether clear and there is a possibility of falling into error in formulating conclusions concerning the relation between fatigue and typhoid fever. In the first place exhaustive physical exercise, as for instance after prolonged forced marches with raw troops, may cause a continued fever which resembles typhoid fever clinically, but is wholly different in its etiology and pathology. This fever of exhaustion may continue for two or three weeks and is frequently mistaken for typhoid fever, but it never occurs in epidemic form, that is, it never spreads to those who have not undergone the fatigue. It has been observed that within two or three days after a forced march or other exhaustive exercise the number of typhoid fever cases increases. The short time elapsing between the exercise and the appearance of the fever does not justify the belief that infection occurred during or after the exercise, but in many of these cases infection must have occurred before the physical exercise, and the only effect attributable to fatigue is that of causing the more speedy development of the disease in persons already infected. It is true that physical exhaustion may and probably does increase susceptibility to typhoid fever. This is brought about by lowering the resistance of the body to infection.

*Influence of Social Position.*—Typhoid fever is not more prevalent among the poor than among the rich. Indeed, it frequently prevails more extensively among the better-to-do classes than among those suffering from poverty. It was frequently told us while making our inspection of camps in 1898 that companies recruited from the wealthier classes had more typhoid fever than those from the working classes. In some instances we found this apparently true; in others it was only an opinion not supported by facts. In some instances men having money indulged more largely in the purchase of articles of food and drink from outside vendors, and in this way the dangers of infection were increased. However, in civil practice it is observable that typhoid fever is not a disease of poverty, but on the other hand, it is quite as likely to afflict those who are pecuniarily well-to-do. Furthermore, this disease is more prevalent among the well-nourished and robust than it is among

those of more delicate constitution. I have already endeavored to point out that man is most susceptible to this disease in early adult life when he is supposed to be possessed of the greatest vitality. The full-blooded, vigorous man is quite as likely to fall a victim to this disease as his anemic weak brother. So far as the influence of vocation is concerned, there is no evidence that one occupation more than another creates a special predisposition to this disease, except in so far as the occupation brings the individual into more frequent and dangerous communication with the specific cause of the disease. Physicians, nurses and laundresses show a large percentage of typhoid fever, but this is due to the fact that their work brings them into close contact with the stools of typhoid fever patients.

*Influence of Cold.*—It is quite widely believed that exposure to cold increases susceptibility to typhoid fever. In most reported cases supposed to illustrate this point the fever follows so closely upon the exposure that the infection must have occurred previously. The probabilities are that in most of these cases the supposed exposure to cold arose from the chilly sensation likely to accompany the prodromal stage of this disease.

*Influence of other Diseases.*—The Influence of other diseases upon susceptibility to typhoid infection is interesting, but is also one about which we must be slow to draw conclusions because the evidence is likely to be misleading. Curschmann states that the acute infectious diseases, especially during the febrile stage, protect against infection with typhoid fever. He has also observed that during convalescence from other acute infectious diseases there seems to be partial and temporary immunity to typhoid fever. These opinions are based upon personal observations in several great epidemics, notably that of Hamburg from 1885 to 1888, in which 15,804 cases were reported. However, we must bear in mind that one sick of scarlet fever or some other acute infectious disease is not for the time being exposed to typhoid infection to the same extent that healthy people are. The Hamburg epidemic was due to an infected water supply, and it is more than likely that individuals suffering at that time from other acute diseases drank proportionately less unboiled water than healthy people did. However, there may be truth in Curschmann's observations. I simply suggest caution in accepting them as conclusive. The same great clinical teacher has observed that persons with tuberculosis in an advanced stage seldom become infected with typhoid fever in spite of the fact that tuberculous patients are often kept for long periods in the same hospital wards with typhoid fever cases. He thinks, however, in these instances the immunity to typhoid fever should be chiefly attributed to the emaciation accompanying tuberculosis, and he states that typhoid fever is also rare among those suffering from malignant diseases, from constitutional disorders, and especially from diabetes. The belief that the immunity to typhoid fever observed in advanced cases of tuberculosis is due to emaciation rather than to specific infection with the tubercle bacillus is supported by the observation that infants with latent tuberculosis fail to show this immunity to typhoid fever, and he adds that every physician of experience has unfortunately had opportunity to observe the rapid progress of tuberculosis in such cases during illness with typhoid fever. He states that individuals suffering from chronic nervous disease, in so far as these maladies occur among those of susceptible age, show no immunity to typhoid fever.

Certainly with our present knowledge concerning the etiology of typhoid fever, no one will hold that this disease is ever caused by errors in diet or by the consequent gastric or intestinal catarrh. However, there still remains the question whether or not acute catarrhal conditions of the stomach and intestine place these organs in a better condition for the reception and retention of the typhoid bacillus. When the three members of our board began the investigation of the cause and spread of typhoid fever all of us believed that special attention should be given to the study of the relation between preceding gastro-intestinal disturbances and typhoid fever. At that time we were of the opinion, which seems to be quite generally held, that acute disease of the gastro-intestinal tract renders the individual more susceptible to subsequent infection with typhoid fever. However, our studies forced us to come to the following conclusions concerning the relation between typhoid fever and preceding temporary intestinal disorders, including those diagnosed as diarrhea, enteritis, gastro-enteritis, gastro-duodenitis, intestinal catarrh, gastro-intestinal catarrh, gastric fever, and simple indigestion.

1. The temporary gastro-intestinal disturbances of May and June (it will be remembered that the troops went into encampment late in April or early in May and continued in the service until September or October) had but little effect upon subsequent infection with typhoid fever. We mean by this that men who are reported as having such temporary disorders during the time mentioned were found to be no less and no more susceptible to subsequent infection.

2. The temporary gastro-intestinal disturbances of July and August gave a certain degree of immunity against subsequent infection with typhoid fever.

3. The majority of men who developed typhoid fever did not report at sick call previous to the appearance of this disease.

4. In a considerable percentage (a little more than one-third) of the cases which are reported as having been preceded by some intestinal disturbance the preceding illness was so closely followed by typhoid fever that we must regard the former as having occurred within the period of incubation of the latter.

In order to show the evidence upon which the above given conclusions are founded, I quote from our unpublished report the following statements:

We have investigated the medical history of each of 12,484 men at Chickamauga. With the names of these men before us we have ascertained the complete medical history of each one so far as the regimental and hospital records show.

Of these 12,484 men, 5237 had some intestinal disturbance. As has already been stated, the names given to these intestinal disorders by the surgeons were numerous and diversified, but we have included all under the general head of gastro-intestinal disorders.

The 5237 men who had some intestinal disorder furnished 672 cases of typhoid fever. This shows a percentage of 12.83. The 7247 men who had no recorded intestinal disturbance furnished 2091 cases of typhoid fever. This shows a percentage of typhoid fever among these men of 28.85.

These figures show that the men who had temporary intestinal disorders furnish less than one-half as many cases of typhoid fever as did the men who had no preceding intestinal disorder, but the above given figures are misleading because of the 672 cases of typhoid fever that occurred among men who had had some intestinal

disorder, in 265 the recorded intestinal disorder is so closely connected with the subsequent typhoid fever that it must be regarded as a part of the prodroma of typhoid fever.

A corrected statement would read as follows: 4972 men who had had some preceding intestinal disorder furnished 407 cases of typhoid fever. In other words, the percentage of typhoid fever among the men who had had temporary intestinal disorders was 8.18; 7512 men who had had no preceding intestinal disorder furnished 2356 cases of typhoid fever. In other words, the percentage of typhoid fever among the men who had had no intestinal disorder was 31.36. The facts might be stated in another way as follows: Among 2763 cases of typhoid fever, 2356 were not preceded by any intestinal disorder, or the percentage of cases of typhoid fever which were not preceded by any intestinal disorder was 85.27.

To my mind the only explanation that can be given to the immunity, which was apparently due to gastro-intestinal disorders, is that these temporary disturbances were typhoidal.

## A SYNOPSIS OF THE SANITARY CENSUS OF MANILA.

HARRY L. GILCHRIST, M.D.

First Lieutenant and Assistant Surgeon U. S. Army; Late Chief of the Sanitary Department, Board of Health, Manila, P. I.

MANILA, P. I.

Early in January, 1901, the President of the Board of Health of Manila, under the authority of the Provost Marshal General, ordered the sanitary census of the city to be taken and a report of the same to be made. The undertaking was difficult in the extreme. Obstacles peculiar to Oriental cities were met on every side.

The work, however, was essential for the better government and sanitation of the city. Manila had now been in the possession of the United States a little over two years. At the time of our entrance the city was in the usual filthy state characteristic of most Spanish cities, and was also in the midst of an epidemic of smallpox, which was everywhere apparent. One of the first orders issued by the Commanding General was the establishment of a Health Board, and the suppression of the smallpox epidemic was the first thing that received the attention of the board. A vaccine farm was established and a hospital erected for the treatment of these cases. Later the dirty streets, alleys, parks and public buildings were attended to. It was not until August, 1899, that the Board of Health was thoroughly organized, and Major Guy L. Edie, Surgeon, U. S. Army, was chosen as its president. Under his personal supervision the different departments were established, reputable physicians and midwives were employed to attend to the indigent sick, and free dispensaries located throughout the city; a uniformed sanitary brigade, a corps of public vaccinators, and a system of street scavenger carts was organized. Competent inspectors of markets, foods, buildings, etc., were employed.

As the work progressed and the duties in the different departments increased, it became apparent that little was being accomplished, owing to the utter lack of information concerning the location, modes of life and surroundings of the inhabitants. To remove these difficulties and also to ascertain the population of the city the sanitary census was ordered.

To understand more clearly the contents of this article and the scope of the work accomplished, attention is called to the accompanying map, a photograph of the original sanitary map of Manila.

Owing to the irregular lay of the city, its densely crowded condition, and the mixed nature of its population, the work of taking the census could not have been accomplished by following the methods adopted in the larger cities of the United States. After numerous consultations with those thoroughly acquainted with the subject the following plan was adopted:

1. The division of the city into districts, sections and blocks.

2. The work to be accomplished by sections separately, a census-taker to be assigned to each block.

3. In order to secure accuracy, a numbered and illustrated chart of each block was made, showing the location of every house within the block for checking off purposes in the final compilation.

4. The staff of census-takers to be divided into day and night forces for reasons hereinafter stated.

It was not till Jan. 25, 1901, that the printing and other preliminaries necessary for the work were ready. Meantime a corps of intelligent natives, selected as census-takers from the excellent sanitary brigade, were carefully drilled and instructed in all that appertained to their duty. On this date the actual census-taking was begun, and so energetically was the work prosecuted that by the end of June it was entirely completed.

#### OBSTACLES TO BE OVERCOME.

It was the original intention to record each family and the names of its members, but it was early discovered that this was impossible, owing to the fact that a large proportion of the native population had no family names. A record in sexes, numbers and races was substituted, this being the only feasible thing to do. Another great difficulty, one which often proved a serious hindrance to the work, was the characteristic suspicion, or superstition, with which the census-taking was regarded.

The homeless population, including those who worked on the bay during the day and slept under promiscuous shelter along the river front during the night, was a third difficulty which the census-takers found hard to overcome, owing to their great numbers and roving disposition. On one occasion more than 300 males were counted sleeping under the porches and around the large piles of boxes and barrels surrounding the government "go-downs."<sup>1</sup> These men worked along the river front and in the quartermaster's warehouses and obtained their subsistence from the numerous street vendors scattered throughout the district. As this class could not be interviewed by the day force, it was the duty of the night men to discover and enumerate them.

#### THE CITY BOUNDARIES.

The city boundaries were those laid down by the military governor. Commencing on the north, they extend from a line drawn through the Boca de Vitas to Lico, a

1. Go-downs are large one-story warehouses usually built of brick or stone and covered with corrugated iron roofs. They are used for storing hemp, rice and sugar.

part of which is included, then across to the San Juan river, passing just to the outer side of the Chinese Hospital, taking in Block Houses 4, 5, 6 and 7; to the San Juan river to its mouth; the Pasig river to the outlet of the Estero Concordia; the Estero Concordia to Block Houses 10 and 11; then the Estero Tripa de Galinas to the road passing Block House 14 to Manila bay on the south. (Map is not extensive enough to show these.)

In compiling this work some very insanitary places have been discovered, brief mention of which will be made later.

Before entering into a detailed description of the various districts of the city attention is invited to the following quotations of Notter and Firth. Under the subject of "Tenement Houses" and under the Public Health Act of 1875, Section 90: "The minimum free air space allowed for rooms used for sleeping purposes should be 300 cubic feet for every person exceeding 10 years of age, and 150 cubic feet for those under that age," and "for all apartments not used for sleeping purposes the minimum air space should be 300 to 400 cubic feet, and for every 80 cubic feet of air space within a room there should be one square foot of window or door space." Munson's "Military Hygiene," 1901, says in regard to barracks in the tropics: "Each man should be allowed 90 feet of superficies and 1800 cubic feet of air space."

Attention is now called to the various districts into which the city is divided, and which may be compared to wards in American cities.

*San Nicolas.*—The San Nicolas district was chosen as the starting place, being the largest in population. It is, however, the smallest in area of any district in the city. The district lies on the northern side of the Pasig river at its mouth. In area it occupies about one-fourth of a square mile, but has a population of 46,280 inhabitants, living in 5181 buildings, none of which are more than two stories high; 828 buildings are in good condition, but contain only a small portion of the population, while they cover a large part of the area of the district. The rest of the buildings are poorly constructed and ventilated, and in most cases, horribly overcrowded. Commencing at the Bay, one of the worst blocks in the district is that known as the "Farola." Here were found nearly 1800 people, living in small rudely constructed shanties, built over the Bay, back of the river front. This was the starting-point of the last cholera epidemic which visited the city ten years ago. Working gradually toward the center of the city, another very insanitary place is the double block of nipa shacks<sup>2</sup> occupying the territory between Calles Vives, Lavezares, Principe and the Bay.

The first section of this block faces on Calles Vives, and has an area of 20,250 square feet, on which are crowded 60 nipa shacks, the only shelter for nearly 800 people. The block is extremely unhealthy and insanitary, due not only to the crowded condition, but to the situation. The ground being very low, the tide washes over the greater part of it, and the place is always in a filthy state. The second section of the block is in even a worse condition than the first, it being not only subject to tide washes, but is the outlet of the overground sewer on Calle Principe, the main drainage

2. A nipa shack is a small thatch-covered house, built of bamboo framework fastened with pegs and tied with rattan. It is covered with the dried leaves of the palm. These houses are constructed in various shapes and sizes, and are generally raised from 4 to 8 feet above the ground on bamboo posts. Entrance is gained by means of a small bamboo ladder. The doors and windows are constructed of like material.

of the whole district. The area of this section is 35,154 square feet, and has a population of 1776 people living in about 80 shacks. The inhabitants are mostly poor native fishermen.

Calle Ylang Ilang is a very narrow street, only 16 feet in width, extending from Calle Jaberanos to Calle Laverares, a distance of one-fourth of a mile. It is built up on both sides with solid running one and two story dilapidated tenements, occupied almost entirely by Chinamen who operate opium dens, chow stands and disreputable houses. These dwellings are appallingly overcrowded. In apartments of not over 10 feet front, 8 feet high and 20 feet deep, from 40 to 50 Chinamen were found huddled together on the floor and shelves surrounding the room. The ventilation of these places is wretched, the only opening in the most of them being the small door in front, which is generally closed with the setting sun. Plague has existed in this district ever since its first appearance two years ago, and still furnishes a large number of cases. At the corner of this street and Calle Jaboneros there is a large 2½ story tenement house occupied principally by Chinese. On the ground floor is the usual opium dens and dirty eating stands; on the second and third floors are disreputable joints and cheap lodging places. This building contains nearly 800 people. The sanitary arrangements of the place are very poor. There is only a limited supply of water, and practically no sewerage system. The blocks bounded by Calles Jaboneros, Camba, San Nicolas and Asuncioni; Calles San Fernando, Elcano, Jaboneros and Asuncion; the Chinese row on Calle Jaboneros near Calle Madrid; Calle Jaboneros between Calle Elcano and Santo Christo; different sections of Calle Santo Christo, Calle Fundidor; the district back of the city slaughter house, and numerous other places, space not permitting mention, are in a terribly crowded condition—25 to 50 people having been found crowded together in small ill-ventilated rooms of not over 1800 cubic feet, with no other ventilation than the small door used as an entrance. Within the district are a large number of warehouses and go-downs, nearly all of the army store houses, including the quartermaster and commissary depots, sub-station board of health,<sup>3</sup> the Port Captain's office, the new steel market house, and the San Fernando police station. The streets are clean and in good condition; they run at right angles to each other, are well illuminated at night by electric lamps, and are sprinkled during the dry season. The rather limited water supply is obtained from the city water works,<sup>4</sup> numerous wells and cisterns. The closets used are of the old vault system and are very insanitary.

There is practically no sewerage system except the open gutter drains which empty into the nearby esteros, and in many cases these drains are in bad condition, accumulated in stagnant pools, and seething with germs of disease.

3. These stations are established throughout the city, and are in telephonic communication with the main office of the Board of Health. All sanitary work connected with the various districts is done through these offices. Ambulances and disinfecting wagons are attached to each. They are in charge of a competent chief inspector, and from four to eight sub-inspectors assist him in the various duties connected with the sanitation of the district.

4. Manila's limited water supply is piped in from the Mariquina river, a distance of nine miles. During the dry season this stream is very shallow. Many small barrios or villages are built on its banks (above the intake), and the water from this stream is used for all their purposes. A recent examination of the water obtained from different places above the intake was found by Dr. Calvert to be polluted with bacteria. The wells are very shallow—not more than three to five feet deep—and the water obtained from them is brackish and unpalatable. The numerous cisterns existing are generally built of brick or stone and cement lined, and are above ground. They are of sufficient capacity to retain water enough to last from one wet season to the next. This water is considered to be the best.

*Tondo.*—This district lies just north of San Nicolas and extends to the city limits on the north. Nipa shacks predominate throughout, with here and there a few good buildings. The district has a population of 33,003, nearly all being Filipinos; there are 2112 Chinese. The populated part is the southern section, very few living in the northern two-thirds. Within the district are numerous ruins of the fire of Feb. 12, 1899, when the insurgents tried to burn the city; many caribou sheds, a large cemetery, the terminus of the Manila and Dagupan Railroad, the Tondo Cathedral, the Cuartel de Meisic and the old Tondo Market, which is the largest and most insanitary place in the city. This market is composed of many badly constructed, closely packed and insanitary nipa shacks, where from 5000 to 10,000 natives congregate every market day. The northern section of the district is composed mostly of swamps, tide-flows and rice paddies. The rebuilding in the section destroyed by the fire has been carried on without restriction, to such an extent that some streets have been obliterated entirely. There is no sewerage in this district, the usual results prevailing. The water supply is obtained from the city water works, numerous wells and cisterns and street carts. Few closets exist, and those are of the vault system, the natives using the bay, beach, swamps, rice fields, and in a few cases the hog scavenger closet is still retained. Owing to the lack of a crematory in this part of the city, the rubbish, refuse, etc., is dumped near the center of the district, between Calle Lemery and Salcedo, giving rise to very offensive odors. The district is poorly lighted, the only illumination on many streets is that furnished by the natives themselves by means of small cocoanut-oil lamps suspended in the front of their houses. During the rainy season a large part of the district is inundated.

*Binondo.*—This district, which embraces the business section of Manila, joins San Nicolas on the east and is about the same in area, extending almost to the San Lazaro Hospital. It has 34,361 inhabitants, and 1469 buildings of all descriptions. The district is thickly inhabited, and contains the largest Chinese population of any in the city. Viewed from a sanitary standpoint, Carvahal Alley is easily the worst place in the district. This alley is about one-sixth of a mile long, and varies in width from 4 to 10 feet. On either side are one and two story dilapidated buildings, occupied by hordes of Chinese who conduct opium dens, chow stands, etc. False floors exist in all these places to the great detriment of sanitation and the health of the occupants. In the rear of these places are shacks of all varieties, furnishing shelter to large numbers. Plague has been prevalent here since its first appearance.

Many other sections in this district are in an overcrowded and insanitary condition, notably the blocks bounded by Calle, San Vicente, Neuva, San Jacinto and Dasmarinas.

The solid running buildings facing the numerous alleys which extend from Calle Rosario to Calle Neuva are not only in an overcrowded condition, but these thoroughfares being only 3 or 4 feet in width, sunshine is an unknown factor; hence these places are always dark and damp, and extremely unhealthy. Sub-station No. 2, of the Board of Health, the postoffice, two theaters, the Orient and English Hotels, the Insular Cigar Company, the large Binondo Church, many warehouses and go-downs are in this district.

The sewerage system is very poor, only a few small sewers existing on some of the larger streets, which empty into the nearby esteros and Pasig river. The

closets are of the old vault and flush vault system, mostly the former, and generally in bad repair. The water supply is obtained from the city main, and a few wells and cisterns. The streets are clean, well illuminated, stone paved and in good repair.

*Santa Cruz.*—This district extends from the Pasig river and Estero San Jacinto to the city limits on the north, and contains some good buildings, many nipa shacks, San Lazaro Hospital, two theaters, Santa Cruz Church, Convent, and Cemetery, the Plague Hospital, Sub-station No. 3 of the Board of Health, and the Bilibid Prison. The population of the district is 34,333; four-fifths are Filipinos, the remainder are mostly Chinese. There are 2140 buildings in the district; Calle Bilibid, a very wide street, divides the district in the center. The buildings on the south side are in good condition; those on the north are mostly nipa shacks. The most thickly populated parts are Calle Bulumbayan, along the Estero San Jacinto, Calle de Lacoste, Calle Trinidad and Calle Dolores. The majority of the buildings in this section are of good material, two stories high, but all densely populated. The Chinese joints are on Calles San Jacinto, Obando and Dolores, the usual insanitary conditions in Chinese quarters prevailing. The streets are clean and in good condition. The district is well illuminated at night. There is no sewerage system. A few much neglected sewers exist in some streets. These empty into the adjacent esteros. The water supply is obtained from the city water main and numerous old wells, cisterns and water venders. Most of the closets are of the vault system and very insanitary. In the north section the open fields, rice paddies and esteros are used for closet purposes. Numerous cases of plague have been found in this district. The ground is very low. At high tide during the rainy season the district in many places is covered with water ranging from six inches to two or three feet.

*Quiapo.*—Quiapo extends from Calle de Bilibidon on the north, to the Pasig river on the south. In the district are 16,282 people, the greater part being Filipinos. There are 2905 Chinese. The remainder of the population is made up of Americans, Spaniards, etc. There are 1205 buildings, nearly one-half of which are constructed of good material and two stories high. Nipa shacks constitute the greater part of the remaining buildings. The section west of the Cuýtido is thickly populated. Here are many small, ill-ventilated, densely overcrowded stores and stands.

In the northern section are numerous rice fields and pasture lands, which are inundated during the rainy season. The streets occupied by Chinese are Calles Echague and Villalobos, and are in the usual Chinese fashion as regards sanitation. The electric light plant, San Sebastian church, the Oriental cigar factory, and numerous warehouses are in this district. The only sewerage is a few surface drains on some of the streets. The few closets are mostly of the vault system. The water supply is obtained from the city water works. Most of the streets are in good order, clean and well illuminated at night.

*Sampaloc.*—This is the most eastern section in the city and takes in all that territory east of the Calle Iris and Santa Cruz district. It has a population of 22,005 and contains 2229 buildings, all but 300 being native shacks. The district is the largest in area north of the Pasig river, and has many fine residences, the Sta Mesa Hospital, vaccine farm (where most of the virus used in the islands is prepared), sub-station No. 5 of the

*San Miguel*.—The district of San Miguel extends from the Pasig river on the south to the Esteros San Miguel and Sampoloc and Sta Mesa on the north. The population is 8185, of whom 1075 are Chinese. Of the 715 buildings two-thirds are shacks. The thickly-populated section is along Calle San Miguel and part of Calle

This district is entirely covered with buildings, no vacant lots existing. Some of the buildings are densely crowded. The streets are narrow, but well kept and well illuminated. The area of the district is less than one-fourth of a square mile. The poor sewerage system

Within the district are numerous fine residences, headquarters of the Department of Luzon, the Governor-General's residence, Nurses' Home, Women's and Children's Hospital, San Miguel brewery, and several lumber yards and sheds. There is no sewerage system. Most of the water is obtained from the city water works. The closets are of the flush vault system, the better class of residences having the flush closets, which empty into the nearby Pasig river. A large whisky distillery and several tobacco factories are in the district. The streets are in good condition and well illuminated at night.

*Ermita*.— Extends from the walled city and Bagumbayan on the north to Calle Herran and an imaginary line continuing to the Ermito Estero on the south. It embraces that section sometimes called Concepcion. The population is 8747, many of whom are Americans.

5. The moat is the walled in trench, varying in width from 30 to 300 feet, which surrounds the old wall on the outer side. This moat, which formerly contained eight feet of water, has been allowed to fill up until at present it is in a condition similar to the many esteros, filled with deposits of all kinds and very insanitary.

There are 1238 buildings, of which 970 are of the nipa variety.

Within this district are the Luneta, Malcon drive, Ermita church, sub-station Board of Health, Hospital No. 3, a large observatory, exposition grounds, First Reserve Hospital, and the very dilapidated and insanitary market adjoining, with many fine residences along the bay shore. Numerous rice fields are in the eastern portion. The nipa section is the only crowded part of the district. The main streets are wide and in good condition. There is no sewerage system. The water is taken from the city water main. The closets when present are of the flush vault system, the natives using the esterios and rice fields. Some of the main streets are lighted by electric lamps, but, in the native section, the only illumination at night is the small cocoanut-oil lamps.

*Malate.*—This district extends from the southern boundary of the Ermita to Paco on the east, to Manila bay on the west, and to the city limits on the south. The population is 5831. Over three-fourths of the 748 buildings are nipa shacks. This is the largest district in area south of the Pasig river. The resident portion is along the bay shore. There are no thickly crowded sections. In the districts are the Second Reserve Hospital, Malate barracks, several fine residences, Fort San Antonio, cable station and the Malate church. This being an outlying district, the greater part of it is under cultivation. The streets are in good repair, and the main thoroughfares well lighted. The city water works and numerous wells supply the water. The closets when present are mostly of the vault variety. There is no sewerage system.

*Paco.*—This district occupies the southeastern section of the city of Manila, and is one of the largest south of the Pasig river. It extends from the boundaries of Ermita and Malate to the city limits, with the exception of the most eastern part, which is known as the village of Pandacan. The population is 11,380, and the number of houses is 1380, of which 1278 are constructed of nipa. There are no thickly populated parts. In the district are many ruins of the fire of Feb. 12, 1899, also some fine residences and the works of the Germinal Tobacco Company, Paco cemetery and a large crematory.

*Pandacan.*—This district is practically a small village just outside the second mile circle. The population is 2839, all of whom are Filipinos. There are 543 buildings, most of which are nipa shacks, built closely together. A large church and convent are in the district. There is no sewerage system. The Pasig river and some wells supply the water.

The city of Manila is built on a low tract of land consisting of an alluvial deposit at the mouth of the Pasig river; a network of unsightly and insanitary esterios or canals practically make it a city of islands, none of which are over four feet above high-water mark. These esterios are utilized for various purposes and are subject to tide changes. At full tides they are used for the navigating of small bancos, scows, rafts, etc. At low tides they are beds of filth and muck, giving rise to the most sickening odors; at all times they are used as sewers and catchalls for the immediate vicinity, also for washing, bathing and in some instances for drinking purposes. The latitude of Manila is 15 degrees north. The temperature is from 65 to 97° F. in the shade. April, May, June and July are the hottest months; December and January the coolest. The greatest rainfall occurs in July, August, September and early

October. The average rainfall during the year is 75 inches, and it rains 130 days out of the 365. The inhabitants are mostly Filipinos and Chinamen, with a scattering of Spaniards, French and Chinese mestizos or halfbreeds.

The principal articles of diet are rice and fish. The clothing, which is light, is prepared from the fiber of hemp, pine-apple and cotton. The Filipino is very clean about his person and attire, but entirely the opposite regarding his place of abode and general surroundings. As most of the native houses are built from 4 to 8 feet above the ground and the floors of the slat variety, the disposal of slops, refuse and fecal matter was a simple problem until American occupancy, the ground beneath being a seething mass of corruption and generally a good stamping place for the family pigs that grew and fattened there until sufficient size to be taken to the market. (This method of disposal of slops is frequently spoken of by Americans as the hog-scavenger, a few of which are still in operation in some of the outlying localities.)

The Chinese, on the other hand, especially the coolies, or laborers, are filthy in regard to their person, dress and general surroundings, and are great believers in darkness, confinement and absence of water, air and sunshine. They generally live in dark, damp and ill-ventilated rooms, containing numerous false floors or shelves.

The prevailing diseases are: malarial fever, called by the natives calenturia; tuberculosis of the lungs; marcesuela or convulsions, which is very fatal among children; dysentery, diarrhea, beri-beri, bubonic plague and an occasional case of smallpox.

The population of Manila has been greatly exaggerated. Former estimates gave from 300,000 to 600,000 people, but on studying the city and noting the location and small living accommodations, the vast areas of unutilized ground, rice fields, etc., one will see that it could not possibly have contained the number of people thought to have existed there. Taking the Palace within the Walled City as a center, nearly the entire population of Manila lies within the mile and a half circle, which would make it three miles from north to south, and, as this center is near the shore of the bay, one-half of the area is water. Two-thirds of the population occupy a strip of land one and a half miles long by half a mile wide, just north of the Pasig river. South of the Pasig river, the area being about the same as that of the north, contains but 44,122 inhabitants, of which nearly 15,325 occupy the space inside the old walls or the Walled City. As the limits of Manila are nearly five miles from north to south, it will be seen that a large part of the city is covered with rice paddies and cultivated fields.

Its sanitary situation under the present condition is only fair. Until a sewerage system is established, the unsightly and insanitary esterios filled up, the old moat surrounding the Walled City cleaned out, and many of the old dilapidated buildings removed and improvements made on the others, especially in regard to their crowded state, the sanitary condition of the city can not be improved upon.

As a result of the taking of the sanitary census immediate steps were taken under authority of the Provost Marshal General to enact such laws and regulations as would gradually place the city in a better state of sanitation, especially in regard to the overcrowded condition.

The photograph accompanying this article was taken

from the Sanitary Map, size 8x9 feet, which was made and compiled at the time. It is an accurate map of the city and shows the location of every house, hut, outhouse and insanitary place in the city; separate sanitary cards were made also for each premise, containing not only a complete record of sanitary information but a plan of the same.

The total population of Manila, exclusive of officers and men of the army and navy, was found to be 244,732, and the number of buildings 19,463, divided as follows: Americans, 8461; Filipinos, 181,361; Chinese, 51,567; Spaniards, 2382; British, 201; German, 226; Swiss, 78; Portuguese, 52; Japanese, 203; Turks, 16; French, 66; Indian, 53; Russian, 13; Italian, 13; Australian, 4; Arabs, 12; Chilean, 3; Malaysian, 5; Cuban, 10; Mexican, 5; Uruguay, 1. Total, 244,732.

The total number of buildings are the following: Good buildings, 3739; poor buildings, 1135; small buildings, 1333; shacks, 13,256. Total, 19,463.

# AGREEMENT BETWEEN THE HISTORY OF YELLOW FEVER AND ITS TRANSMISSION BY THE CULEX MOSQUITO (STEGOMYIA OF THEOBALD).\*

CHARLES FINLAY, M.D.

HAVANA, CUBA.

(Read on Feb. 19, 1902, before the Pan-American Sanitary Congress.)

The early history of yellow fever, notwithstanding the scarcity and vagueness of the data referring to the first 150 years after the discovery of America, enables us to establish a very plausible connection between the earliest undoubted epidemics of yellow fever, described by Du Tertre and by Cogolludo in the fourth decade of the seventeenth century, and the previous ones which, under the names of "plague," "pestilence" and "malignant fevers," usually attacked the newly-arrived Spaniards at Santo Domingo, Terra Firma and Vera Cruz, ever since the conquest of Mexico in 1519, as also between those same fevers and the "modorra-illness" or "pestilential modorra" which had been recorded, under similar circumstances, at Santo Domingo and at Darien, during the first twenty-five years after the discovery.<sup>1</sup> If this connection be accepted, the unavoidable inference must be that, since the American Indians have no natural immunity against yellow fever and that disease had never been known among Europeans before coming to America, there must have existed, before the discovery, endemic

foci of yellow fever on this side of the Atlantic offering climatic conditions suited to the development of the yellow fever mosquito and enabling that insect to perform its functions as transmitter of the disease. As may be gathered from the contemporary chronicles of Las Casas, Oviedo and Herrera, such endemic foci did exist in the Island of Santo Domingo (Hispaniola) and on the coasts of Venezuela (Nueva Andalucia) and Columbia (Castilla de Oro) ever since settlements were made in those places by newly-arrived Spaniards. As a rule, the disease broke out in its full force during the summer months and, after a lull during the cooler season, it would break out again the following summer, until all the new-comers, having once suffered an attack remained thereafter proof against that illness.

The most significant statement which I have been able to find in order to connect pre-Columbian epidemics suffered by the aborigines with those which subsequently attacked the Spanish invaders, occurs in the *Chronicles of Herrera*,<sup>2</sup> which he published in 1599, eighty years after the conquest of Mexico. In chapter 6 he explains "how it happens that the country of Vera Cruz and that northern coast is so sickly \* \* \* from April till September, at which time those who go out in the sun to attend to their business are taken sick \* \* \* while in the months from November till March, the weather is cold \* \* \* and, the earth being then dry, the country becomes as healthy as it is in Mexico (City), and those who arrive at that time are safe not to suffer." Chapter 8 is headed: "About the cocolitzle sickness, and wherefor the northern coast of New Spain is so scantily peopled," and it opens thus: "It has already been stated that the city of Vera Cruz and all the northern coast is sickly, owing to its hot climate which makes the illnesses more deadly \* \* \* and children can not be reared in it because any disorder gives them fever; this is why the population there is so scanty. If in Montezuma's time its population was so numerous, notwithstanding that the same general diseases (epidemics), called "cocolitzle" prevailed, and in some years more than in others, as happens now, that was due to the fact that Montezuma, in view of the mortality and scarcity of inhabitants in that part of the country, used to collect from Mexico and other parts, where the population was numerous, eight thousand families \* \* \* and sent them to the places where the cocolitzle had been severe, giving them houses and lands and exempting them from taxes for a term of years; in this way the coast was repopled, whenever it became necessary, with those who were not needed in the places from which they had been taken. So also the name cocolitzle has been given to general diseases of smallpox, which they have suffered, and to universal plagues."

I wish to call particular attention to Herrera's remark: "as happens now," referring, no doubt, to the year 1598 in which he wrote—whereby he identifies the "pestilence" which, up to that time, the newly-arrived Spaniards suffered every summer in Vera Cruz, with the "cocolitzle" which in Montezuma's time attacked the inhabitants of the high plateaux around the City of Mexico who had been sent to repopulate the coast upon which Vera Cruz was subsequently built. Both diseases were annual and prevailed in the summer season, as does now yellow fever in the same spot, after the lapse of three and a half centuries. It was not, therefore, without good reason that a belief prevailed among the inhabitants of

\* My own experiments of yellow fever inoculation, ever since 1881, when I decided to submit my mosquito theory to a practical test, have always been performed with the domestic day mosquito of Havana. I had previously consulted the distinguished Cuban naturalist, D. Felipe Poey, about the classification of the samples which I showed him, and he informed me that from similar samples which he had taken to Paris in 1817 or 1820, the species had been named "culex mosquito" by Robineau Desvoidy. D. Felipe had previously called the insect "mosquito de Cuba" (Cuban mosquito). The experiments made by Drs. Reed, Carroll, Agramonte and Lazear were started in June, 1900, with a brood hatched from eggs of the identical insect which, at Dr. Lazear's request, I had handed to him. All the successful experiments have hitherto been made with that particular mosquito.

From a medical point of view, it would be quite illusory to admit, *a priori*, that other mosquitoes, whose external and functional characteristics differ materially from those of the culex mosquito of Desvoidy, share with the latter the faculty of transmitting yellow fever, even though they should happen to belong from the naturalist's standpoint—to a common group or species, such as the *Stegomyia fasciata*, of Theobald.

So far as I can judge from the written descriptions by former classifiers, the culex mosquito (Desv.), *culex tenellus* (Wied.), and *culex elegans* (Flc.) represent but one identical insect, and must therefore be considered as the "yellow-fever mosquito." About the other synonyms included in the *Stegomyia fasciata* species, in the absence of direct experiments of inoculation, the faculty of sexual reproduction between males and females classed under different headings, should be resorted to before prejudging their capability of transmitting the disease.

1. "Epidemiologia primitiva de la fiebre amarilla," in *La Cronica medico-quirurgica de la Habana*, May 15, 1897.

2. *Chronicles of Herrera*, 1599, Chaps. 6 and 8, Book 9, 4th Decade.

Vera Cruz that yellow fever had existed there ever since the foundation of the City—as Humboldt was informed when he visited the place at the beginning of the nineteenth century.

If Montezuma had in view the protection of the coast of his empire against foreign maritime invasions, when he adopted a measure which seemed well calculated to maintain alive the cocolitzle infection, he must have relied upon its success and cherished the hope that, after having by his dilatory policy induced Cortés to remain on that coast from April till the middle of August, the Spanish leader would have been forced to abandon his enterprise in consequence of the havoc which the Mexican cocolitzle would have made among his soldiers. That Cortés had not to submit to the sad fate, which befell General Leclerc in Santo Domingo in 1802, must be attributed to the circumstance that the 600 Spaniards who came with him had previously gone through epidemics of “modorra” at Darien and at Santo Domingo; another proof being thus afforded that the two names belonged to one identical disease.

On the American coast and islands—with the exception of the Island of Cuba—where the Spanish discoverers made their first settlements, those who came for the first time to America had always to reckon on the “modorra” or “pestilence” which, as a rule, attacked them in the summer months. The propagation of the infection was not generally limited to the seaboard, as happened on the coast of Vera Cruz; this difference arising from the peculiar orography of the Mexican territory, on the one hand, and, on the other, from the circumstance that the modorra or cocolitzle disease, like our modern yellow fever, was only transmissible within moderate altitudinal limits above the sea level. Mexico, indeed, differs from the other places mentioned above by the fact that its shores toward the Atlantic consist of a comparatively narrow strip of lowlands at the back of which rises a continuous wall of highlands, altogether beyond the reach of those pestilences which I claim to have identified as our modern yellow fever. That condition of things did not occur along the shores of Santo Domingo (Hispaniola) nor of Darien, so that no obstacle existed there to prevent the propagation of such epidemics from the coast to the interior. The Indian population was very numerous, before the discovery, on the islands as well as upon the continent. They lived in crowded huts, forming separate villages—some of them with 1000 or 2000 inhabitants, of peaceful habits and devoted to agriculture, but ever ready to change their dwellings or to scatter in the woods whenever danger was apprehended from enemies or from some contagious disease. Under these circumstances it will be readily understood how, upon the occurrence of an epidemic of yellow fever, many would escape from the contagion, but the germ would spread over a wide area, and, by reason of the mild winters, the infection would not be easily extinguished.

The final confirmation of the rôle which appertains to the *Culex* mosquito Desv. (now included in the genus *Stegomyia* of Theobald), in the transmission of yellow fever, has now been sanctioned by the experiments of Drs. Reed, Carroll, Agramonte and the lamented Dr. Lazear, at Quemados de Marianao during the winter of 1900, afterward by those of Dr. Guiteras at the Experimental Station of Las Animas, last summer, and finally by the splendid practical results obtained by the Chief Sanitary Officer of Havana, Major W. C. Gorgas, during the epidemic-year which has just been completed.

With those facts and the ones which I had gathered in former years, it is now possible to determine with some degree of precision the conditions which are necessary in order that yellow fever may develop in an epidemic form in a given locality, not too highly situated above the sea level and where temperatures between 25 and 35 C. (77 and 95 F.) either temporarily or habitually prevail. A distinction will, however, have to be made between localities in which the yellow fever mosquito already belongs to the fauna of the place, and others in which that species of mosquito does not habitually exist. The conditions, in either case, may be reduced to three. They will be, in the first instance, as follows:

1. Presence of a yellow fever patient within the first 5 days of his attack and exposed to be bitten by mosquitoes, or else the mere importation of one or more contaminated mosquitoes.

2. Abundance of mosquitoes of the required species, so that some of them will be likely to reach a yellow fever patient in a condition to become contaminated.

3. Presence of persons liable to contract the disease and so placed that they may be bitten by the contaminated mosquitoes.

In the second instance, when mosquitoes of the particular species did not previously exist in the locality, the conditions will be:

1. Introduction of mosquitoes of the required species, previously contaminated or under such circumstances that they may become contaminated from yellow fever patients simultaneously or subsequently introduced.

2. Circumstances which may enable the contaminated mosquitoes which have been introduced to continue inoculating a series of non-immunes during a sufficient length of time to allow the insect to develop a new brood, so that the new generation of yellow fever mosquitoes may come out in time to contaminate themselves from some of the patients inoculated by their predecessors.

3. The same conditions as in number 3 above.

Whenever two of the above conditions have been fulfilled without any outbreak of the disease following, the other condition must be supposed to be wanting; and, vice versa, if an epidemic of yellow fever does develop, the third condition may be supposed to have been fulfilled even if not actually demonstrated, unless the reverse can be absolutely proved.

Instances of the first class are, for obvious reasons, by far the more frequent; they include the epidemics recorded in the southern states of the Union, in the South of Spain, in the Canary Islands, in the Balearic Islands, Western coast of Africa, Italy (Leghorn in 1804), in all of which countries mosquitoes of the yellow fever species are known to exist. As instances of the second class may be cited the epidemics recorded in the northern parts of the United States, in Saint-Nazaire (France), in England, in Canada (Quebec), Madrid (Spain), in which countries the outdoor temperatures are only suited for the active functions of the yellow fever mosquito during a limited period, and even then may not be such as would allow the reproduction of successive generations of that insect.

Inasmuch as the only natural means by which yellow fever is, so far, known to be propagated, consists in the inoculation of the pathogenic germ through the bites of contaminated mosquitoes, the propagation of the disease across the sea would, in many instances, be inconceivable unless those insects have some propensity to take up their abodes inside of vessels and to thrive in

them, even when confined within the hold during a considerable length of time. A confirmation of this fact has recently presented itself; the Mosquito Commission of the "Orleans' Parish Medical Society" having reported that five mosquitoes of the "*Stegomyia fasciata*" species had been found last summer in the hold of a fruit vessel just arrived in that port. Indeed, there is a possibility that such a thing did occur as far back as Columbus' first voyage of discovery. After discovering and exploring the island of Santo Domingo, he sailed from the coast of Higüey on Jan. 11, 1493, for Spain, but on February 14, his carabela having been assailed by a terrible hurricane since the 12th, he was so exercised over the thought that he might yet be unable to convey the glorious news of his discovery that, he wrote, a great fear took possession of him and every mosquito sufficed to worry and disturb him. If that expression is to be understood literally and Columbus was referring to the hours of night, the mosquitoes which worried him were probably our "pungens," otherwise they must have been our day mosquito, the regular yellow fever mosquito, those two being the only species whose domestic proclivities would have been likely to induce them to board the admiral's carabela while it lay close to the shore of Santo Domingo. The following year (1494), also, there is collateral evidence which induces me to infer that contaminated mosquitoes must have been conveyed from Santo Domingo to the Canary Islands, the homeward trip at that time being made along that route. From historical data which I had set down in my recent paper,<sup>1</sup> I had come to the conclusion that the first name given by the Spaniards to the epidemic which caused so many deaths among them, at Santo Domingo in 1494, had been "modorra pestilencial"; a name which I had never met before (as applied to any human disease) and only once again with reference to the severe epidemic, of the same kind, which attacked the Spaniards who went with Pedrarias Davila to Darien in 1514, until a short time after the publication of the aforesaid paper<sup>1</sup> when I accidentally came across the following remarkable passage in Humboldt and Bonpland's Travels<sup>3</sup>: "What remained of the Gaunches (in the Canary Islands) perished mostly in 1494, in consequence of the terrible pestilence called the modorra, which was attributed to the number of dead bodies left exposed to the air by the Spaniards after the battle of La Laguna." On Feb. 2, 1494, Antonio Torre had sailed from Santo Domingo for Spain, bringing Columbus' full description of his second voyage to that island and also Dr. Chancas' interesting letter telling of the many men who had latterly been taken sick, though he felt very hopeful that their illness was not a dangerous one. It proved otherwise, however, for that was but the forerunner of a terrible epidemic to which I understand that the name of "modorra pestilencial" was given. The obvious inference is, therefore, that some of Antonio Torre's vessels had harbored mosquitoes which had bitten, in Santo Domingo, patients of modorra. The contaminated insects must have been left at the Canary Islands and there developed the epidemic among the Gaunches which is mentioned by Humboldt and Bonpland.

The following instances may be cited to show the coincidence of a remarkable abundance of mosquitoes and great mortalities among the Spaniards in Hispaniola and on the coasts of the Spanish main, within the first decades of the discovery of America.

In Hispaniola, after referring to another outbreak of the usual scourge (1502-1503) on that island and to the yellow color which the patients retained for many days, Herrera<sup>4</sup> goes on to describe the fauna of Santo Domingo, and incidentally mentions "the mosquitoes which are there very troublesome." In 1509, on the coast of Venezuela, when Nicuesa attempted to establish his governorship of Nueva Andalucia, according to Las Casas,<sup>5</sup> "the men who were left at the Belen river died in large numbers and were greatly distressed by the mosquitoes." In Darien, in 1514, Pedrarias Davila's nephew having been sent to reconnoiter the Cenu river, with 200 men, these began to sicken and die, and, adds Las Casas, "being new to the country, they were devoured by the mosquitoes." Finally, on the coast of Mexico, where Vera Cruz now stands, Bernal Diaz del Castillo, notwithstanding his previous experience at Darien, complained very bitterly of the intolerable torment caused by the mosquitoes.

On the Island of Cuba, on the contrary, the abundance of mosquitoes is not particularly emphasized by the early chroniclers and it so happens that on this island the earliest outbreak of a fever which bore any resemblance to yellow fever occurred in 1620, during the summer months only and never recurred again till 1649; but this time with a more permanent character. Pezuela<sup>6</sup> refers to it in these terms: "In the spring of 1649, the city (Havana) was thrown into consternation by a horrible epidemic. Since the smallpox which had decimated the newly-settled towns in this island at the beginning of the sixteenth century, it had known no contagions nor illnesses, excepting those which properly belonged to its hot climate and the malignant fevers of the summer of 1620," and he adds: "In July and August (1653), Santiago de Cuba and Bayamo were afflicted with the same fevers which, three years before, had caused so many deaths in Havana." From those data, it must be inferred that the yellow fever mosquito did not originally belong to the fauna of this island, but that gradually a race of the species developed in Cuba, capable of accommodating itself to its climate which is somewhat cooler than that of Santo Domingo or of Vera Cruz; otherwise it would be difficult to account for the fact that having a sufficient non-immune population and notwithstanding that the three regular fleets (*flotas de India*) from the infected ports of Carthagen de Indias and Portobello, from Honduras and from Vera Cruz, met each year at Havana in June, before proceeding on their return trip to Spain, 100 years elapsed after the first Spanish settlements were made in Cuba before yellow fever made its appearance on this island.

In Campeche and Merida de Yucatan, on a parallel corresponding to that of the center of the Island of Cuba, the first epidemic of yellow fever, after its occupation by the Spaniards (1547) occurred in 1648, and its description by an eye witness, the Historian Cogolludo, is indeed more accurate and detailed than any that had previously been published in any language. Since then epidemics of yellow fever have at different times broken out in Yucatan, the yellow fever mosquito having apparently adapted itself to the climate of Yucatan one year sooner than to that of Havana.

Farther toward the equator, in the Guianas, where the Dutch made their first settlements in 1580, I have no information regarding the early medical history of that

country; but in 1763, an expedition of colonists having been sent by the French Government to Cayenne, most of them died of a fever which, according to Béranger Féraud, could have been no other but the yellow fever.

South of the equator, on the coast of Brazil, the first epidemics on record are those of Bahia and Pernambuco (Recife) in 1686; but the facility with which it extended in the neighboring country shows that the yellow fever mosquito must have already existed there. Not until 1850 did yellow fever extend as far south as Rio de Janeiro; it has, however, been endemic there ever since. The present limits of the endemic yellow fever zone, so far as latitude is concerned, may therefore be placed at the 23d parallels, north and south of the equator.

In equatorial Africa, through the slave trade with the West Indies, endemic centers must have developed soon after the discovery of America; and some have persisted to this day, principally in the French colonies on the west coast, notwithstanding the racial immunity which most of the indigenous races possess.

Beyond the Atlantic shores, yellow fever epidemics have only been recorded in some ports of the Mediterranean and on the Pacific coast of South and Central America. The fact that no permanent endemic focus has ever developed on the Pacific side of the American continent, is a curious feature which must probably be attributed to the following circumstances: 1, the necessity of crossing the mountain range of the Andes in traveling from the Atlantic to the Pacific coast and, 2, the cooler temperatures which usually prevail along the western coast of South America. The first of these conditions impedes the spontaneous migration of contaminated mosquitoes across the highlands, while the cooler temperatures may prove incompatible with the development of successive broods of the particular species, on the Pacific coast, except at certain epochs, when unusually high temperatures have been known to occur during several successive years.

#### CONCLUSIONS.

As the outcome of the above historic and etiologic considerations I beg to submit the following conclusions:

1. The endemic foci of yellow fever in America, from the pre-Columbian times to the beginning of the seventeenth century, were comprised within a zone between the 20th and the 8th or 9th parallels of north latitude, reaching, toward the east, as far as the Leeward Islands and limited toward the west by the Atlantic coast of the American continent. During the seventeenth century, that zone extended farther north up to the 23d parallel and southward to the parallels of Bahia and Pernambuco. Finally, in 1850, it reached Rio de Janeiro.

2. The transportation of mosquitoes of the yellow fever species, in sailing vessels, appears to have been of frequent occurrence, ever since the early times of the discovery of America. To it must, probably, be attributed the coincidence of the severe epidemic of the so-called "modorra pestilencial" in Santo Domingo, in 1494, with another very fatal epidemic of the same name, in the Canary Islands, the same year. Apart from the conveyance of contaminated mosquitoes, healthy ones must have been frequently imported into subtropical countries, where they are found now to exist, having acclimated themselves to their new abodes. This is known to be the case in Italy, in the south of Spain and coasts of the Mediterranean, as well as in the South of the United States and in other countries. The previous existence of the yellow fever mosquito must be con-

sidered, *per se*, to constitute a dangerous complication whenever a case of yellow fever happens to be introduced in a place usually free from that infection.

3. The range of the Andes and its prolongation along the Isthmus of Panama and Central America, appears to have stood as a barrier, protecting to some extent the western coast of America against the migration of contaminated mosquitoes. That obstacle, however, is about to disappear when the Panama or the Nicaragua canal comes to be opened; let us hope, therefore, that, by that time, through the joint efforts of all the nations interested, all the existing foci of the disease will have been extinguished and that the adoption of measures, similar to those which have proved so successful in the hands of our sanitary department, will henceforth provide reliable means for controlling the propagation of yellow fever.

#### THE DIAGNOSTIC VALUE OF TUBERCULIN.

C. M. WOOD, M.D.

PHYSICIAN TO COOK COUNTY HOSPITAL FOR CONSUMPTIVES.  
DUNNING, ILL.

As a general proposition it may be said that prompt accurate diagnosis is the most difficult and at the same time the most important thing in medicine or surgery.

This is especially true in the matter of tuberculous diseases. Recognized early, they are very largely curable; recognized late, the prognosis is relatively and almost absolutely bad. In other words, in tuberculosis the promptness of the diagnosis very largely determines whether the given case shall result in recovery or death. If, then, early diagnosis is of such great importance; if it enables us to transform a hopeless disease into one which is in a large measure curable, it behooves us to make use of every harmless means within our power to discover the lesion and determine its nature at the earliest possible moment. The microscope, the stethoscope, the clinical thermometer and the tape measure are in the hands of every physician; their value is admitted and when properly used they will, as a rule, make possible a definite diagnosis at the time of the first examination.

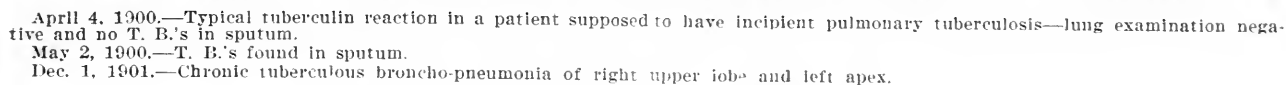

However, there are cases of tuberculosis where there is no sputum nor discharge for examination; where the stethoscopic findings are inconclusive; where there is no fever nor deformity. In these cases, where all other signs fail, we have an aid so searching, so harmless and in my opinion, so helpful, that I wish to urge for it a much more general use among the profession. I refer to the hypodermic injection of tuberculin.

In 1890 Koch first advocated tuberculin as a remedy for tuberculosis. When it was found later that it would not cure the disease the majority of the members of the profession abandoned it and now that it has found its place as an aid to diagnosis they refuse to reconsider it.

Much has been written on the value of tuberculin as a diagnostic measure, and its use has been advocated by some of the best men in the profession. Nevertheless, it has not been employed as generally as it should be. There are several reasons for this. 1. We habitually neglect to use all the diagnostic resources at our command. 2. It was formerly thought that the administration of tuberculin, even in moderate doses, might aggravate the disease. 3. The reaction is not always clear and definite. This, however, is usually due to insufficient dosage.

The principal objection urged against tuberculin is its supposed possibilities for doing harm. It is no doubt true that the enormous doses given in the first years of

Number of cases injected, 100; number of false reactions, 6; percentage of error, 6 per cent.

its use as a remedy sometimes did injury. Mention is made by Muir and Ritchie of the injection of 25 c.c., which is 1600 times the dose necessary for the diagnostic reaction. With such huge doses it is quite possible harm may have resulted.

In approximately 250 cases, some of these receiving as much as .015, I have watched carefully for any unfavorable effect in the course of the disease. In not a single instance did the diagnostic dose either accelerate an active process or light up a quiescent one.

Also in cases complicated with nephritis, cirrhosis of the liver, endocarditis, typhoid fever and pneumonia no harmful effect could be detected. In tubercular meningitis however (and this is the only exception), it is quite probable that the local reaction might do serious damage by increasing the intracranial pressure.

Objections to tuberculin on the grounds of unreliability can not however be answered so readily. Tuberculin is like the stethoscope—it gives the evidence but the verdict must be decided by the diagnostician.

Appended to this paper is a table of 100 cases in which tuberculin has been given for diagnostic purposes. All cases have been under observation for a year or more after the injection or else the case has earlier taken such a course that the findings based on the tuberculin injection could be either confirmed or disproven. From a study of this list of cases I have formulated for my own use the following requirements for the diagnostic reaction:

1. The rise in temperature must amount to at least 2 degrees.

2. It must reach its height between 6 and 24 hours after the injection, except in fibroid cases, where it may be delayed to 36 hours.

3. It must be accompanied by at least two of the following symptoms: chilliness, headache, nausea, and muscular pains.

When the list is examined it is found that 41 cases gave a reaction meeting these requirements. Of the 41 cases 36 were subsequently proven to be undoubted cases of tuberculosis: 3 were syphilitic, and 2 were profoundly neurotic.

In something less than 50 per cent. of cases syphilis gives a reaction which can hardly be distinguished from that of tuberculosis. However, this seems to be the case only when syphilis is still active enough to give manifest signs—one case by Dr. Otis, of Boston, to the contrary notwithstanding. Consequently, in any case showing a reaction, active syphilis should be excluded before it is decided that the case is tuberculous.

In the neurotic cases the symptoms were wildly exaggerated, in one case the temperature reaching 108. The other case reacted later with almost equal intensity to a hypodermic injection of sterile distilled water. In these cases the reaction had no diagnostic dignity.

It is said that a reaction sometimes follows the injection of tuberculin in cases of leprosy, actinomycosis and a few other diseases, but these occur so infrequently in this country that they seldom enter into the problem.

Of the 100 cases 59 failed to show a reaction that would meet the above mentioned requirements; of these only one subsequently showed evidence of tuberculosis, although all were under observation for from one to three years.

In this single case the injection was made only four days prior to death at a time when the bodily powers were unable to react to any irritant.

This list is short: the number is small, but since every

case was followed until it made manifest its tuberculous or non-tuberculous nature it gives us some idea of the reliability of tuberculin and the essential symptoms of the true diagnostic reaction.

Unless the process is undergoing fibrosis the reaction must reach its height in the first 24 hours after injection, most typically at the 18th hour.

#### CHART I.

Slight rise of temperature is inconclusive; 33 of the 58 non-tuberculous cases showed some elevation following the injection, but only in the 3 syphilitics and 2 neurotics did the rise amount to 2 degrees.

#### CHART II.

The rise in temperature in tuberculous cases depends somewhat on the amount of tuberculin injected. The initial dose should be .005 (M. viii of a 1 per cent. solution). If there is no reaction whatever it is probable that tuberculosis is not present. If no symptoms have been produced by this small dose, it is more satisfactory and perfectly safe to repeat the injection, using .010. If with this dose the characteristic reaction does not occur it may be decided with much certainty that the case is not tuberculous.

#### CHART III.

If, however, .005 produces some disturbance, yet less than the characteristic reaction, the dose should be increased by .0025 each third day until .010 is reached or the characteristic reaction produced.

These doses, while somewhat larger than usually recommended, are absolutely safe and will not influence unfavorably the course of the disease. On the other hand the result will be more definite and therefore more valuable than if small doses only are used.

The amounts given above are for Koch's original tuberculin made in Germany; with the Pasteur Vaccine Co.'s tuberculin I have had to use slightly larger doses to obtain the same definite results. Veterinary tuberculin I have not found reliable for human use.

The technic of the injection is as simple as the administration of a hypodermic of morphin or strychnin. A one, two or three per cent. solution may be used, or a solution of the following formula: Koch's old tuberculin made in Germany, m. i, distilled water recently boiled, 5i, 5 per cent. carbolic solution, m. v of this solution m.i = .001 of tuberculin. Before the injection the temperature is to be taken every four hours for at least two days and the temperature during the reaction is to be compared, not with the normal but with the temperature at the corresponding hours on the days preceding the injection. Patient's mode of life, his diet and exercise must not be changed during the days of the test in any way that might influence the temperature.

Tuberculin has its peculiar value in the fact that it is the complement of the microscopic examination. A positive sputum examination establishes a diagnosis of tuberculosis; a negative tuberculin examination, provided a dose of .010 is used, practically excludes tuberculosis.

It can not be denied that patients are more or less uncomfortable for a few hours during the height of the reaction. Headache is the symptom most complained of and it should be relieved by a moderate dose of the bromids, as the coal-tar products interfere with the temperature curve. Chilliness, nausea, muscular pains and sweating occur in various combinations. Seldom are they all present and no symptom except the headache is ever severe. The day after the reaction the patient feels quite as well as usual.

A very circumscribed induration and redness of the skin, very closely resembling erysipelas, will usually surround the site of injection for a few days. This occurs in tuberculous and non-tuberculous cases alike. Abscess formation can always be avoided except in syphilitic subjects, where it is very prone to occur.

The so-called "local reaction" at the site of the tuberculous lesion may be very slight; in fact, even where the general reaction is distinct the local reaction often can not be detected either in affected lungs or joints. In lupus the local reaction is usually distinct.

That tuberculin might sometimes be used to advantage in recognizing advanced, as well as early cases, of pulmonary tuberculosis, is shown by the fact that of the 2240 cases sent to the Cook County Hospital for Consumptives 239, or over 10 per cent., were not tuberculous; 263 showed no tubercle bacilli in the sputum. Of these 24 were proven by the aid of tuberculin to be cases of tuberculosis.

Also in excluding the 239 non-tuberculous cases tuberculin was often of service; for with the microscope and the stethoscope alone it is manifestly much easier to confirm than to disprove a diagnosis of phthisis.

#### CONCLUSIONS.

Tuberculin in doses of .005 carefully increased, when necessary, to .010, produced no bad effects in simple or complicated tuberculous or non-tuberculous cases.

The characteristic tuberculin reaction is shown by a rise of at least 2 degrees in temperature, reaching its height in from 6 to 36 hours after the injection, typically at the 18th hour, and accompanied by at least two of the following symptoms: chilliness, headache, nausea and muscular pains.

The tuberculin test ranks in value with the Widal typhoid test since in the former the technic is simpler; the materials are more readily obtainable and more permanent; the danger is no greater and the information obtained is scarcely less reliable.

### THE PARAFFIN INJECTION TREATMENT OF GERSUNY, WITH A REPORT OF CASES.

RUPERT M. PARKER, M.D.

CHICAGO.

About two years ago a young man, who had undergone a double castration, presented himself to Gersuny<sup>1</sup> with the complaint that, being obliged to go before the military medical board of Austria for examination, it would be humiliating to display his defect.

Gersuny, having incidentally observed, in connection with certain therapeutic measures, that paraffin of a low melting point, when injected into the tissues of the body, remained indefinitely without reaction, conceived the idea of substituting paraffin prosthesis for the absent members. He injected various quantities of paraffin at different times, and accomplished the desired result, which he reported shortly afterwards, together with the details of his technique.

The success of his first trial encouraged Gersuny to make other applications of his treatment. The second patient,<sup>2</sup> a woman, suffered from absolute incontinence of the urine, which had resisted repeated operations for its relief. The urethra was widely dilated and its mucous membrane was prolapsed. Paraffin was injected under the prolapsed mucous membrane and the latter pushed into the bladder so that the deposits of the wax came to rest within the internal meatus. Then a ring of paraffin was injected beneath the skin around the

external meatus, to prevent a recurrence of the prolapse. After injections of various quantities of paraffin at different times, Gersuny finally succeeded in producing complete continence, and at the last report from the patient, one year after the final treatment, urine could be retained from eight to ten hours at a time.

Since the publication of these two cases, other surgeons, as well as Gersuny, have employed the treatment in various pathological conditions. In a case of urinary incontinence in a female, Kapsammer<sup>3</sup> injected the paraffin below the urethra, which was thus crowded upward and arched over the prothesis, a condition resembling that of the hypertrophied prostate in the male. Pfannenstiel<sup>4</sup> reported an unsuccessful attempt in treating a case of bladder insufficiency almost identical with that of Gersuny. He used the same method but deviated somewhat from the original technique and observed the typical symptoms of a lung embolus as a complication, which will be considered later. Halban<sup>5</sup> and Moszkowicz<sup>6</sup> have reported cases of cystocele, prolapse of the vagina and prolapsus uteri with retroversion successfully treated by the injection of paraffin into the vaginal walls and the parametrium. It is self-evident that such an application is permissible only when future pregnancy can with all probability be excluded and when the radical operation must be avoided.

Gratifying results were obtained from the injections for the relief of incontinence of the feces<sup>6</sup> following an amputation of the rectum for carcinoma and after operations for peri-rectal abscess and fistula in ano.<sup>6</sup> Complete continence was secured in the two latter cases, and continence, except for fluid stools, in the former. Three months after the final treatments the good results were still present. Hard feces were passed with difficulty, making it necessary to use enemata and avoid constipation. Paraffin injections have been used to some extent in the treatment of inguinal hernia. Moszkowicz<sup>6</sup> reported two cases of large scrotal hernia which had repeatedly become incarcerated in spite of attempts at mechanical support. The inguinal canal was narrowed from a diameter admitting four fingers to that admitting one, by injections of paraffin into the surrounding tissue. The contents of the sac could then be satisfactorily retained by means of a truss. Seven months after the treatment of one case and ten months in the other the improved conditions were unaltered. Experience has taught in these cases, however, that the paraffin in the loose tissue about the inguinal canal is liable to become displaced and sink into the scrotum unless sufficient time is allowed for its encapsulation before the truss is applied. Gersuny does not consider his method a substitute for the radical operation in the treatment of hernia, but an alternative when the latter is contra-indicated.

Among numerous other applications the injection of paraffin about the ends of a resected nerve<sup>6</sup> has been found useful in preventing their reunion. The introduction of paraffin between the surfaces of a joint after the breaking of an old ankylosis has been suggested to prevent a recurrence of the adhesion. A substance like paraffin which can be easily removed after the joint surfaces have healed is much more suitable than the firmer materials, such as celluloid, silver, tin and rubber, employed by Cklumsky. However, the practical application of paraffin to this purpose has not been sufficient to establish its utility.

Gersuny has found a limited use of his treatment in oral surgery. A small opening between the nose and the

mouth, left after a staphylorrhaphy,<sup>6</sup> was closed by injections of paraffin. In another case following staphylorrhaphy,<sup>6</sup> the velum was too short to be approximated to the posterior pharyngeal wall, so that hard "g" could not be pronounced. Injections under the mucous membrane of the posterior pharyngeal wall and of the uvula caused the former to bulge forward and the latter to elongate sufficiently to overcome the defect.

Most satisfactory and startling results of the treatment are seen in the correction of unsightly deformities following cicatricial contractions resulting from wounds and loss of tissue through disease and operative measures. The resection of the superior maxilla in one patient and of several ribs in another<sup>6</sup> was responsible for two disfigurements corrected by Gersuny. In the latter case the depression was so great that an injection of over two ounces of paraffin was required to fill out the chest to symmetrical proportions. This is the largest amount of paraffin ever injected into the human body. As most suitable for the purpose of filling out smallpox pits and other cicatricial retractions, Gersuny<sup>6</sup> recommends a mixture of four parts of olive oil to one of paraffin. To

The ordinary lump paraffin is much too hard and the paraffin known as white or medicinal vaseline is too soft. These two products may be melted together in proportions to secure the desired consistency, or the liquid vaseline and the lump paraffin may be mixed. The ordinary soft paraffin in lumps and oleum petrolati were used in the treatment of my cases. The melting-point of the mixture was tested with the clinical thermometer. The bulb was smeared with a thin coating of the wax and immersed in a water bath, which was gradually heated until the melting-point was reached, when the wax loosened itself and floated to the surface as a globule of oil, and the thermometer indicated the temperature. My finished product had a melting-point of about 102° F., and its consistency was that of vaseline. It was sterilized, as Gersuny<sup>1</sup> recommended, by heating it at its boiling-point for a few moments. This process is reasonably certain to kill all pathogenic germs, as the boiling-point of the paraffin is much above that of water.

For the purpose of injection an ordinary hypodermic syringe with a large needle might have been used, but as the paraffin hardens and destroys the leather valves and

overcome the defect it is usually necessary to make the depressed area bulge. The oil is absorbed and the surface becomes even. Where the scars are firmly bound to the underlying tissue by adhesions, it is necessary to separate them by means of the bistoury. Moszkowicz<sup>6</sup> and Rohmer<sup>7</sup> have reported the injection of paraffin into the retro-orbital tissue, thereby supplying a deficient support for an artificial eye. In the correction of the saddle nose which has resulted from either trauma or osteomyelitis highly satisfactory results are reported by Moszkowicz,<sup>6</sup> Stein<sup>8</sup> and Heath.<sup>9</sup> The writer also has employed the treatment in the correction of two cases of saddle nose, a report of which follows with a description of the technique used.

The paraffin should have a melting-point slightly above the normal temperature of the body, i. e., between 99 and 104. If it is below the body temperature it will soon be carried away by the lymphatics and if the paraffin is too hard it may cause necrosis, as in the case treated by Foederel. There is no paraffin on the market with the proper melting-point, so far as I can learn.

loosens the cement in the joints around the glass barrels, a syringe constructed entirely of steel was found more serviceable. The syringe was aspirated full of the melted paraffin, inverted, and the piston pressed upward sufficiently to expel any bubble of air present in the cylinder. The needle was then screwed firmly on its attachment and, to prevent its contents from hardening too rapidly, the instrument was placed in hot water until needed. Just before inserting the needle for injection, the syringe and its contents were tested by strong, steady pressure on the piston. If the needle had become clogged, the obstruction was removed by a strand of fine wire. The paraffin was allowed to cool sufficiently to flow from the needle, not as a liquid, but as a worm-like, semi-solid, coherent string. The patient, as a rule, required no preparation beyond the usual antiseptic precautions. When the tissue to be injected was very dense and inelastic, the injection of paraffin was preceded by one of Schleich's solution, which served to anesthetize the region and at the same time dilate the lymph spaces in anticipation of the paraffin. The needle was always

introduced at some distance from the seat selected for the prosthesis and then carried under the skin to the desired point. If the needle were inserted through the skin directly over the prosthesis, more or less paraffin would escape through the tract of the needle after its withdrawal. The paraffin was distributed as desired by changing the position of the needle-point while an assistant molded the prosthesis with the fingers as it was deposited in the tissue. The skill required in the injection and distribution of the paraffin was previously acquired by a few experiments on animals.

CASE 1.—This was a patient of Dr. E. B. Fowler, to whose courtesy I am indebted for the opportunity of presenting this case. Wm. T., aged 25, received a traumatic injury of the bridge of the nose eleven years ago. The deformity which resulted is shown in photograph No. 1, taken immediately before the first injection. On Dec. 6, 1901, 2.5 c.c. of paraffin were injected by Dr. Fowler and the writer. The point of the needle was inserted under the skin on the dorsum of the nose, slightly below the level of the eyebrows, and pushed as far downward as it was desired to begin the prosthesis. The result of the first injection is shown in photograph No. 2, taken immediately afterwards.

The pain experienced was inconsiderable; no anesthetic was required in this or subsequent treatments. The reaction was at its height two days later and consisted in a feeling of tension in the skin of the nose, slight frontal headache, some erythema and a moderate amount of edema of the nose, spreading somewhat upon the face. December 15 the reaction had so far subsided that a second injection was permitted. With the needle inserted at the tip of the nose, .5 c.c. was injected. The reaction was less than by the first treatment.

The patient presented himself again on Jan. 5, 1902. Although the curve of the bridge was uniform, he was not yet satisfied, as the nose was very broad at the base, and out of proportion to its height. Another injection of .5 c.c. was given. The prosthesis has gradually increased in hardness until now it has the consistency of a cartilage.

CASE 2.—Mrs. C. presented a deformity of the nose, shown in photograph No. 4, as the result of an ulceration nine years ago, which destroyed the whole cartilaginous septum and the cartilages of the alae. An injection of 1 c.c. of paraffin on December 8 corrected the saddling completely, but the collapsed condition of the alae remained unimproved after repeated injections, owing to their lack of support. The reaction following

the injections in this case was very slight. Infiltration of Schleich's solution preceded the paraffin injections into the alae, on account of their dense, inelastic tissue. The results of the treatment in both cases were most gratifying to the patients and their friends.

Several objections have been raised to the injection treatment of Gersuny. Meyer<sup>10</sup> holds that the paraffin is more or less toxic and his contention is corroborated to an extent by the experimental work of Straume,<sup>11</sup> Dunbar,<sup>12</sup> Stubenrath<sup>13</sup> and Sobieranski.<sup>14</sup>

On the other hand, Stein<sup>8</sup> injected liquid vaseline under the integument on the backs of white mice, in quantities equal to one-third their body weights. No rise of temperature or other constitutional disturbance followed. Only one mouse died and that from mechanical injuries. Whether the constitutional disturbances observed by the other investigators, above mentioned, resulted from mechanical injuries in the administration of large quantities of the coal-tar oils, or whether the injury was of a toxic nature, matters little so far as the Gersuny treatment is concerned. The amount of paraffin is relatively so small and its absorption, if it occurs

at all, is so slow that toxemia from the paraffin injected for surgical purposes is not to be feared.

Meyers<sup>10</sup> also objects that the paraffin used by Gersuny will be eliminated from the body by absorption. To prove this he carried out a series of experiments on animals, but admits that his results were not conclusive. Juckniff<sup>15</sup> found that non-watery fluids like liquid vaseline, when injected into the bodies of animals, are not directly taken up by the lymph vessels, but undergo a fine subdivision by the ingrowth of connective tissue and are finally converted into emulsions, the small globules of which are held in the meshes of the connective tissue and finally carried away by the lymphatics. In the margins of an old paraffin prosthesis the same histological process was seen by Gersuny. No case has been observed long enough to decide whether the paraffin finally undergoes absorption or not. In Gersuny's oldest case<sup>6</sup> no diminution in the size of the prosthesis could be detected after two years. From this we know that if elimination of the paraffin does occur it is a very slow process. The objection from Werthmuth, that

paraffin injected into the pelvic tissue may become displaced by coitus and obstruct the ureters by pressure. is more theoretical than practical. At least no such accident could occur after the prothesis has had two or three weeks' time to become fixed by encapsulation.

Another and a more credible objection to the treatment is the danger of lung embolism if the paraffin is injected directly into a vein. In Pfannenstiel's complication of lung embolus following the injection of 30 c.c. of paraffin, the case ran a mild course with recovery. Friends of the treatment blame Pfannenstiel's technique for the accident, inasmuch as he used paraffin with a melting-point of 113. They claim that in order to inject 30 c.c. of such paraffin at one injection, a much higher temperature would be required to prevent hardening before the process could be completed, and that the degree of heat may have caused coagulation in a vein, hence the embolus. The experience of the dermatologists with the injections of mercury suspended in liquid paraffin and other allied oils is instructive as to the dangers of embolus in the paraffin injections. Harttung<sup>16</sup> saw only one case in 8000 intermuscular injections, and Möller observed 28 in 3835 cases. He then changed from inter-muscular to subcutaneous injections, and found no embolus in 240 injections. Neisser<sup>18</sup> had one among 800, and Epstein only 7 among 8292 subcutaneous injections. The majority of the cases of emboli following intermuscular and subcutaneous injections of oils are very mild, with transitory symptoms and I know of no fatal case ever reported. When a semi-solid paraffin is injected, it is reasonable to expect fewer emboli than have occurred with injections of oil.

From the results of the paraffin injection method of Gersuny already obtained. I think it justifiable to claim for the measure a permanent place in the treatment of appropriate cases. Even though future experience proves a slight danger from lung embolism, the treatment will find application in cases which can not be relieved in any other way, and in those in which other measures are far more dangerous or absolutely contra-indicated. It may be that the paraffin is slowly absorbed, but many patients will gladly submit, at long intervals, to so mild a measure for the relief of defects which are social stigmata, when they would shrink from the dangers of a more severe operation.

## A NEW COUPLER FOR RAPID INTESTINAL ANASTOMOSIS.\*

EVAN O'NEILL KANE, M.D.

KANE, PA.

The variety of mechanical devices and stitches recommended for intestinal anastomosis is so great as to sufficiently prove all to be inadequate. The loss of one of my patients in whom I placed a Murphy button, on account of a plum skin occluding its small aperture like a valve, brought forcibly to my notice the danger in its employment. The loss of two others, however, in which I subjected them to the shock incident to prolonged exposure of the intestines during suturage with mauling and bruising and needle puncturing common in such cases, made me still unwilling to lay aside Murphy's contrivance.

I began a series of experiments seeking to elaborate some device which would possess the advantages of the Murphy or the Frank button but with an aperture of ample dimensions and admitting of a larger and wider intestinal overlap. I determined, also, to do away with stitching of any kind and to make leakage impossible. After much work and experimentation I believe I have succeeded in producing a coupler that answers every purpose, at least until something better can be devised.

I have as yet employed this latest modification of my coupler upon but one human subject, a boy who unfortunately died three days after operation from a general septic peritonitis (result of a neglected typhlitic abscess and requiring a resection of gut for gangrene), too soon therefore to allow of the complete detachment of the coupler. In this case, however, a firm union by lymph exudate had taken place around the entire circumference while a rarifying necrosis had already commenced in the portion compressed between the flanges. Among the living animals upon which I experimented were two dogs and three cats, all of which made perfect recoveries. They passed their couplers at periods varying from three to five days after the insertion, with the exception of one cat, which disposed of its coupler when out on a ramble, the precise date not being known.

The principles essential to assure success are as follows: 1. Rapidity of execution. 2. A patulous canal with a caliber sufficient to make occlusion impossible. 3. No possibility of leakage. 4. Apposition of serous surfaces around the entire lumen. 5. A sufficient overlap to insure obtaining sound live gut within and about the field of union with active circulation. 6. The least amount of handling during the necessary manipulation. 7. The least number of needle punctures and suturage. 8. Simplicity of construction and application such as will render its employment intelligible and applicable by any novice. 9. It should not be large enough to make it a source of obstruction after it becomes detached.

My coupler consists of three cylinders, two outer and one inner one. The latter has a length equal to that of both the former, which are large enough to slip easily over it, besides allowing a layer of gut to be interposed. The inner cylinder has a depression around each end and a projecting flange. The distal margins of the outer cylinders are incurved to the same caliber as that of the inner one. The proximal margins are also inverted but only to a sufficient degree to enable them to catch upon the flange of the inner cylinder when they are drawn apart. By means of two perforations opposite each other in the incurved distal surfaces of each of the outer

\* Read and demonstrated before the McKean County Medical Society, Dec. 12, 1901.

cylinders and others in the flanges at each end of the inner one, extra strong braided linen threads with knots at the ends to prevent their slipping completely through, are passed, brought together across the middle of the inner cylinder and twisted loosely into a half tie. The method of application is as follows: A severed end of gut, the mesenteric attachment of which has been cut or pushed back one or two lines, is seized firmly at four equidistant points by hemostats and drawn over one of the outer cylinders, the coupler having been previously pulled as widely apart as the flanges will permit. Leaving an assistant to hold the intestine drawn thus over the outer cylinder the operator passes a strong silk ligature around the gut immediately behind the beaks of the hemostats and after making two half turns pulls tightly upon it until the encircled gut is firmly buried in the groove around the end of the inner cylinder. A second tie is now made to prevent the thread loosening and with a scissors the ends of the thread are cut short. At the same time the scissors cut off any redundant portions of gut held in the jaws of the hemostats, which are now removed. A similar procedure is next carried out with the other severed portion of gut upon the opposite outer cylinder. Thorough lavage

Coupler drawn together.

Coupler open.

Longitudinal section of coupler.

with sterile salt solution is here resorted to before folding under shall take place. Then the operator, passing the index finger of each hand through one of the loops of the approximating ligature of the coupler, pulls firmly upon them with a slightly zigzag motion until the outer cylinders are drawn so snugly together as to bring the intervening margins of the inverted serous intestinal surfaces into an even and accurate apposition around their entire circumference.

In completion a reverse half turn is made in the approximating ligatures, the knot drawn tightly, and the ends cut off short. It will be observed that the knot is hidden deeply between the serous intestinal surfaces and approximated cylinders so that by lightly pressing back the protruding ends of ligature with a scissor blade or other dull-edged instrument, there is no thread left visible at any point.

As with Murphy's and similar devices so with my

coupler; the approximated serous surfaces of gut rapidly adhere by lymph exudate, but my coupler does not permit any possible leakage (owing to the ends of gut having been first tied firmly down within the grooves at the extremities of the inner cylinder). It therefore requires no suturing of serous surfaces and produces a more perfect and smooth union. It becomes detached and is passed like other contrivances, but unlike them one need feel no anxiety regarding that occurrence because of its relatively small diameter in proportion to its central opening. While it remains adherent there is less danger of stoppage as the opening is much wider than that in any other mechanical device. My objections to a coupler of decalcified bone are that it is hard to make and can be used only once; it is expensive and it swells after its introduction. I see no necessity for an absorbable contrivance when a metal one is so unlikely to become lodged after detachment.

Drawing the coupler together by pulling upon the approximating ligature after the gut has been tied over.

End of gut being tied down into the groove in one extremity of the coupler, the other end having been already tied.

Instead of traction cords I have tried the employment of notched springs on the same principle as with the Murphy button, but while this makes the work a trifle simpler and more rapid it necessitates firm pressure being made upon the ends of the coupler through the gut thus confusing it. This is a serious objection to the Murphy button and one entirely obviated where apposition by traction is employed as it is both in the Frank button and in my coupler. My coupler made of aluminum is very light, one-fourth or less the weight of a Murphy button of the same size. Lightness is an important advantage where the gut to be united is in a much injured condition.

While to the expert abdominal surgeon union by suturing may seem easy and be accomplished with a reasonable amount of rapidity, it is not so with the occasional operator. For him to attempt their applica-

tion is not only puzzling and tedious but, should the case be one of emergency, his work will be well-nigh impossible. The threads become tangled, knotted, twisted and mixed. The gut gets bruised and pulped by prolonged manipulation, devitalized and leaky from punctures and cuts of needles while the surgeon himself becomes exhausted and more tangled up than his sutures.

The "average surgeon," or "occasional operator," as the patronizing expert calls him, will find himself far better satisfied with a simple comprehensive and rapidly applicable device than with one of the above mentioned brilliant and complicated intricacies. To him I would respectfully dedicate my coupler.

## DIAGNOSIS, PREVENTION AND TREATMENT OF PUERPERAL INFECTION.\*

FREDERICK HOLME WIGGIN, M.D.

VISITING GYNECOLOGIST, CITY HOSPITAL.  
NEW YORK CITY.

Thomas Kirkland, Ashby, Eng., in 1774 called attention to the fact that the so-called puerperal fever was a contagious disease. This view was later supported by other independent observers, notably, in 1843, by our own Oliver Wendell Holmes by Sir James Young Simpson in 1846, by Semmelweis in 1847 and by Trousseau in 1856. But it needed the teaching and practical results obtained by Lister, based on the previous work of Pasteur and by the demonstration of the latter in 1880 that streptococci are often found in the lochial discharges of puerperal women suffering from fever and other constitutional disturbances, before obstetric surgeons finally recognized it as a fact that these pathologic manifestations were due to the same micro-organisms, whose entrance into wounds in other parts of the body were followed by similar constitutional disturbances, and that when the wounded maternal parts were kept free from these organisms or their products the puerperal woman during her convalescence was free from constitutional disturbances of a febrile nature.

The practical result of the acceptance of these views and the change in technic in obstetric practice which followed in lying-in hospitals resulted in the practical abolition of epidemics with their high mortality rate, of what was formerly known as puerperal fever, till at the present time, when infection of the mother's wound does occasionally occur, the constitutional symptoms are mild in character, the disease is readily controlled and the mortality rate a fraction of one per cent. Unfortunately, these results have not been achieved by all physicians in private practice and it seems strange that we are obliged to admit that puerperal wound infection in the ordinary daily practice of physicians is of almost as frequent occurrence and is followed by as severe constitutional symptoms and with as high a rate of mortality as it was fifty years ago. Many physicians have been slow to grasp the importance of the principles underlying modern surgical teaching or, while knowing these principles, they have yet failed to apply them to obstetric work and consequently have not profited by them. They are still too often seeking consolation and explanation of the fever and other constitutional symptoms complicating the puerperal convalescence, in the possibility that the disturbance arises from the beginning of lactation or from the specific poisons causing malarial or typhoid fever, instead of attributing those

symptoms to their true cause, in almost every instance, wound infection.

Before considering the diagnosis of abnormal puerperal conditions, it is well to recall the fact that when normal conditions prevail during the puerperium, the pulse rate falls soon after delivery and is slower for a time than usual; that the respirations are normal and that there is little or no rise of body temperature; that increase of pulse rate and of body temperature due to emotional causes rapidly subside, and that similar variations due to an overloaded colon disappear as soon as the bowels move. We should be on our guard, therefore, to quickly recognize that infection of some portion of the wounded maternal parts has almost certainly occurred whenever we find that a puerperal woman during the early days of her convalescence has a pulse rate of 90 a minute or higher, accompanied by a temperature of 100.5 or more, especially if these symptoms continue for more than twelve hours. A careful general examination of the patient should at once be made to exclude inflammatory conditions of the breasts and other sources of error; this should be followed by a local examination and it will probably be found that there are some ulcerating wounds on either perineum, vulva, vaginal walls or cervix, which are covered with a dirty yellowish secretion. If the patient does well for several days and then complains of headache and general discomfort, having at the same time a rapidly rising pulse rate, a chill, a marked elevation of body temperature and pains in the lower abdomen, and if on local examination an enlarged, doughy and tender uterus be found, with its cervix patulous and the lochial discharge purulent in character, with less color than usual, it is reasonably certain that the trouble is due to the most common variety of puerperal infection, endometritis caused by the absorption of the products of decomposition, and that on examining the interior of the uterus a retained portion of the membrane will be found; or there will be discovered a roughening of its inner surface at the placental site caused by adherent portions of the placenta. When the trouble is confined to this region, the course of the disease is limited and in a few days the constitutional symptoms will subside and the disorder become chronic; or the entire endometrium may become involved in the process, in which case the condition is more serious, the constitutional symptoms more marked, the lochial discharge having more odor and less color than in the milder forms of the disease. As a rule, the trouble does not extend beyond the endometrium, but when it does, the evidence of its extension are repeated chills, a daily variation of several degrees of temperature, the usual symptoms of pus formation, the rise of temperature continuing until the abscess is opened and evacuated. The peritonitis following this form of the disease is usually circumscribed. A bacteriologic examination of the uterine secretions will probably demonstrate the presence of staphylococci and establish the fact that the disorder is due to their special action.

When the cause of the septic trouble is due to the direct invasion of the tissues by the streptococci the constitutional symptoms are much more severe in character; the very rapid and weak pulse especially attracts attention, while on the other hand the local symptoms are less marked in character; the uterus on examination is found less sensitive to pressure, of proper size; the cervix is closed and the lochial discharge diminished in quantity or absent, or free from both odor and color. Symptoms of general suppurative peritonitis may be the

\* Read before the New York County Medical Association, Feb. 17, 1902.

first local sign of the infection to attract attention. The symptoms of this serious complication usually manifest themselves between the second and seventh days of the puerperium and are characterized, in addition to the ones already mentioned, by intense pain which at first is limited to the lower abdomen but which gradually extends upward and is accompanied by tympanites. Septicemia, the most fatal form of wound infection, results from the direct invasion of the tissues by virulent streptococci and the absorption at the same time by the tissues of the toxins of decomposition produced by the presence of staphylococci. Its characteristic sign is the great amount of bodily prostration which accompanies the other constitutional symptoms of wound infection. Pyemia manifests itself by the occurrence, ordinarily in the second week of the convalescence, of recurring chills accompanied by a widely fluctuating temperature and the formation of abscesses in various parts of the body. Broncho-pneumonia is a more or less frequent consequence. Phlegmasia alba dolens manifests itself in the second week of the puerperium by pain along the course of one or other of the femoral veins, usually the left, accompanied by swelling of the limb from above downward. When the infection arises from the invasion of the wounded tissues by gonococci, it may usually be determined by the coincident occurrence of ophthalmia neonatorum. The presence of the Klebs-Loeffler bacilli in the wound may be determined by the appearance of the characteristic membrane on the wounded surfaces combined with the usual constitutional symptoms, and confirmed by a bacteriologic examination of the lochial discharge.

The patient's wounds may also be infected by the bacillus coli communis, the pneumococcus and others. It is important, as soon as we are aware of the fact that our patient's wounds have become contaminated, that a bacteriologic examination when practical be made of the lochial discharge, as the information derived therefrom will aid us in deciding the form of treatment to be carried out. Malarial infection can be excluded, as a rule, by remembering the fact that in septic poisoning the pulse rate is higher than the temperature, and by the absence in the blood of Laveran's bodies, whereas in malarial infection they are present and the temperature is higher than the pulse rate. Typhoid fever may be excluded by the absence of the characteristic eruption and the negative result of Widal's reaction.

The causes of puerperal wound infection having been proved to be the result of the introduction into the parturient canal of septic material either before, at the time of or subsequent to delivery, the great responsibility therefore devolves upon the obstetric surgeon of preventing its occurrence, which can ordinarily be done by his bearing in mind a few easily comprehended principles, by the exercise of watchfulness and by attention to a few simple details which are easily carried out even in the homes of the poor. It should be constantly borne in mind by the physician that these germs may be brought in contact with the parts by the act of copulation, by the hands of the patient, nurse or physician, especially if wounds exist in the canal, or by means of unsterilized instruments, syringes used for both enemas and vaginal douches, dirty bedding, linen and towels, neglect to properly care for the patient's body and to empty the intestinal canal.

The nurse selected to attend an obstetric case should be chosen with as much care, if practicable, as one would be for a patient on whom an abdominal operation is to

be performed, or in other words, she should understand the prime importance of cleanliness and be sufficiently trained to carry out the necessary details, as well as to be able to care for the infant; it is as well when possible to have the nurse in attendance on the patient a short time before the expected delivery, and the necessary instructions should be given to her to empty the patient's bowels and to secure a good condition of her skin by means of hot baths, especially that of the external genitals and the anal region, before the expected delivery. At the first indication of labor the rectum should be washed out by an enema of soapsuds and, as soon as this has been accomplished, the mother should be given a final hot bath, after which the genitals and the anus should be washed off with a solution of carbolic acid and the parts protected by a sterilized napkin—or what is better, an obstetric pad—until the end of the second stage of labor has been nearly reached, after this preparation each act of urination or defecation should be followed by again thoroughly cleansing the external genitals and the anal region, by washing them off thoroughly with an antiseptic solution.

The physician on his arrival should be careful to disinfect his hands before making a vaginal examination, and this he can readily do by scrubbing his hands and arms in hot running water, preferably using tincture of green soap and scrubbing them for ten minutes with a fiber brush. The hands should next be immersed in alcohol; the nails being cleansed with a piece of sterilized gauze wet in the alcohol; they should next be immersed in an alcoholic solution of bichlorid of mercury of the strength of 1 to 500, which solution should be removed from the hands by sterilized water before the lubricant is applied to them, which lubricant should be contained in a collapsible tube, or the physician after cleansing his hands may put on rubber gloves that have been boiled for at least half an hour and have then been soaked in a one per cent. solution of lysol. As few vaginal examinations should be made as possible during labor, the required information, after the position of the child has been determined, can be obtained by external examination, with the exception of that relating to the duration of labor. As the second stage of labor draws to a termination, the obstetric pad should be removed, the patient placed on a sterilized sheet and her thighs and abdomen protected with sterilized towels, or with those which at least have been recently washed, and the obstetrician should wear a gown or an improvised one made from a sterilized sheet.

It is, of course, of the utmost importance that the membranes and placenta should be removed intact; the physician should make certain of this by carefully inspecting them after they have come away, and if he finds that portions of either have been retained, he should, after thoroughly sterilizing the external genitals, the vagina and his hand and arm, determine this by an intra-uterine examination, removing them if found; this procedure should be followed by an irrigation of the uterine cavity with sterile salt solution followed by hydrozone. This complication will, however, seldom occur if the physician abstains from administering ergot to his patient until after the delivery of the placenta.

As soon as the labor is over and the patient has had time for a little rest, the physician should make a careful inspection of the perineum, vulva, vaginal and cervical tissues and if any laceration of the parts are found they should be at once repaired and the parts washed

with sterile salt solution and hydrogen peroxid, and protected with sterilized pads. No intra-uterine douche should be given unless it has been necessary to introduce the hand into the uterine cavity. In the after-treatment of the patient under normal conditions, vaginal douches should be omitted, the nurse being directed to keep the external genitals and the anal region in good order by carefully washing and disinfecting them after each act of urination and defecation.

If, on visiting the patient, the physician finds an accelerated pulse and elevated temperature, he should carefully examine her and afterwards make a local examination, first disinfecting his hands and instruments. If he finds an ulceration of the perineum, vagina or cervical tissues, he should thoroughly wash out the vagina with salt solution and follow this with hydrozone or other strong solution of peroxid of hydrogen; if in the judgment of the physician it is necessary to follow this treatment with other irrigations of the vagina, he should administer them himself and not leave them for the nurse. If the septic trouble is more serious in character and is due to the retention in the uterine cavity of decomposed septic material, the patient should be put on a table and placed under the influence of an anesthetic and, after the external genitals and vagina have been carefully disinfected, the uterine cavity should be explored with the finger, which has also been carefully disinfected, or—if the operator is trained and skilful—with the curette, and the offending material removed. The cavity of the organ should then be thoroughly washed out with saline solution followed by hydrogen dioxid and an application of Monsell's solution if the cavity has been curetted. If the operation has been well performed the patient's constitutional symptoms will probably disappear and no further uterine intervention will be necessary. It will, however, probably be best for the physician to give the patient a vaginal douche of saline solution, followed by hydrogen dioxid, once or twice a day for several days. If the constitutional symptoms persist and the condition becomes chronic, it may be necessary to again explore the cavity of the uterus. If the trouble extends beyond the endometrium and an abscess forms, it should be evacuated by means of a vaginal incision, or if there be a bilateral pyosalpinx to deal with, it may be necessary to open the abdomen and remove the diseased tubes and uterus. If it be determined after careful examination that the septic condition of the patient is due to the direct invasion of the tissues by the virulent streptococcus, the physician should, in the writer's opinion, after thoroughly cleansing the external genitals and the vagina of the patient, dilate the cervix and explore the uterine cavity with the finger or with the curette, and then, after thoroughly irrigating the cavity with saline solution and hydrozone, should make an application of Monsell's solution. If the constitutional symptoms of the patient, as the result of this treatment, do not show improvement in a few hours, an intravenous infusion of a considerable quantity of saline solution should be given and the advisability of opening the abdomen and removing the uterus considered, bearing in mind, as has been pointed out by Vineberg, that the uterus is the focus of the disease and that the patient's system will eliminate a reasonable amount of the infective material by the skin, kidneys and intestines; therefore, if the further production of the poison can be stopped, there is a reasonable chance of that already in the patient's system being eliminated and recovery following.

Although a few observers have claimed benefit to have accrued to their patients suffering from this form of infection from the use of Mamorek's antistreptococcus serum, the burden of testimony is against its having been of any avail in these cases; if used, from 10 to 20 c.c. should be injected into the patient's body every 12 hours till she shows signs of improvement, or a reasonable quantity has been used. When from the severe prostration and other constitutional symptoms which accompany it, there is reason to believe that the patient is suffering from septicemia, she should at once be stimulated and given the benefit of a large intravenous saline infusion slowly administered, the temperature of the solution in the reservoir being 120 F., and if she rallies in response to this treatment the vagina and uterine cavity should be cleaned out by thoroughly washing them with saline solution followed by hydrogen dioxid, and the cavities loosely packed with sterilized gauze soaked in ozonized glycerin, which will tend still further to disinfect the parts: the gauze should be removed in from eight to twelve hours and the application repeated. If under this treatment there are signs of improvement, it may be continued at lengthening intervals, or the propriety of more radical measures be considered. If there is no improvement in the patient's condition, further operative treatment will be of no avail. If pyemic conditions are recognized before the onset of pneumonia, there may be some hope under favorable conditions of saving the patient by cleansing and disinfecting the external genitals and vagina, followed by the prompt performance of an abdominal hysterectomy. When thrombosis of the femoral vein occurs, its course should be painted with iodine, the limb wrapped in cotton, bandaged and kept in an elevated position, which should be maintained for two weeks after all swelling has disappeared. Abscesses should be promptly opened.

In the treatment of the various forms of puerperal wound infection there is little to hope for in the use of drugs, except as temporary aids, the physician's reliance being placed rather on the administration of proper nourishment, increasing the activity of the skin, kidneys and bowels, the internal administration of large quantities of saline solution by means of enemas, injections under the skin or into the patient's veins, according to the urgency of the symptoms, and appropriate carefully considered local treatment, which must be decided for each case as it arises.

Curettage and other operative measures should not be universally condemned because when performed by inexperienced and untrained men, or under unfavorable conditions, they have more often been followed by harmful rather than good results. The importance of an early recognition of the fact that the patient's wounds have become infected can not be overestimated, for on this the physician must rely to institute proper local treatment at an early stage of the trouble and before the patient's system is overwhelmed by the poison, for on this must largely depend whether or not the prognosis of the graver forms of the disorder is to be more favorable in the future than in the past.

## TREATMENT OF DIPHTHERIA WITH ANTITOXIN.

The time is long past when there could be any difference of opinion as to the utility of the antitoxin in the treatment and in the prevention of diphtheria and, at the present day, after abundant time has elapsed for the enthusiasm aroused by an important innovation to subside, it may be accepted as the deliberate judgment of the medical profession that the discovery of the antitoxin of diphtheria must rank with that of anesthesia and that of vaccination as among the most beneficent in the history of medicine. Statistical evidence to this effect has been forthcoming in overwhelmingly convincing amount and it would appear almost superfluous to add thereto. Nevertheless, the results of a study of the cases of diphtheria treated in the municipal hospital of Mühlhausen, a small manufacturing city of Germany, both before and since the introduction of the antitoxin are not without interest. Thus, the percentage of mortality from diphtheria was in 1892, 53.4; in 1893, 55.3; in 1894, 51.7; in 1895, 38.5; in 1896, 28.8; in 1897, 16; in 1898, 20; in 1899, 15.1; in 1900, 18.7. Among the cases of pharyngeal diphtheria the mortality percentage was in 1892, 20; in 1893, 35; in 1894, 37.1; in 1895, 19.4; in 1896, 26.2; in 1897, 8.6; in 1898, 14.8; in 1899, 7.1; in 1900, 8.1. Of the cases of laryngeal diphtheria the percentage was among those not operated on; in 1892, 33.3; in 1893, 81.8; in 1894, 58.3; in 1895, 100; in 1896, 0; in 1897, 10; in 1898, 12.5; in 1899, 7.1; in 1900, 8.3; while among those operated on the percentage was in 1892, 67.5; in 1893, 67.7; in 1894, 70.9; in 1895, 70.7; in 1896, 33.3; in 1897, 29.4; in 1898, 35.3; in 1899, 34.4; in 1900, 37. At the same time a large reduction in the number of cases of laryngeal diphtheria requiring operation was noted after the institution of antitoxin treatment. That the favorable results, which correspond closely with those observed elsewhere, are not due to the character of the disease is shown by the fact that the cases during the years 1899 and 1900 were more severe than at any time in the last twenty years.

The plan of treatment pursued consists in the administration immediately of an injection of antitoxin to every child admitted to the hospital, the amount varying with the duration and the severity of the symptoms. Thus, in cases of pharyngeal diphtheria from 600 to 1500 immunity units are given, in accordance with the extent of the deposit, the degree of temperature elevation and the duration of the disease, the same dose or

a smaller one being repeated on the following day and if necessary also on the third day. In cases of laryngeal stenosis, not less than 1500 immunity units are injected at once and the same dose is repeated in from six to twelve hours and possibly from 1000 to 1500 units on the following day. In grave cases, in which the general intoxication is profound, a dose of 3000 immunity units is injected at once. Generally 4000 or 4500 immunity units are sufficient, but in rare cases as much as 6000 units are required. In some cases operative intervention has been averted by the administration of an emetic, the stenosis being, as a result, overcome for a few hours, until the antitoxin has time to exert its influence.

The local treatment in cases of pharyngeal diphtheria consists in the use of gargles of potassic chlorate or boric acid, but in the case of small children, incapable of gargling, local treatment is entirely foregone. Only in severe septic cases are applications of solution of ferric chlorid, 1 to 5 or 1 to 10, made to the pharynx and sprays of antiseptic solutions practiced. The use of the ice collar and the swallowing of bits of ice is practiced only when the glands of the neck are enlarged and deglutition is painful. The general measures consist of rest in bed, a nutritious diet and the treatment of complications. Cases of laryngeal diphtheria and of tracheotomy are kept in a room whose air is saturated with steam.

There are at present few specifics in therapeutics and the antitoxin of diphtheria must be considered one of the most important and most reliable of these. To be most effective it should be employed early and in sufficient dosage. No seriously unpleasant secondary results need be feared from such a course and if these injunctions be observed, we may hope that the mortality from diphtheria, which already has been reduced to half of what it formerly was prior to the introduction and general employment of the antitoxin, will be still further reduced. Even now much of the terror formerly aroused by the development of a case of diphtheria in a household has been removed because of the more hopeful outlook in the individual case and of the powerful weapon for attack and defense that has been placed in the physician's hands in the form of the antitoxin injected for both curative and prophylactic purposes.

## PUERPERAL INFECTION IN PRIVATE PRACTICE.

Maternity hospital statistics show low mortality from sepsis. Private practice, however, still has too many cases of puerperal fever. Often the physician is to blame through ignorance of the proper technique of surgical cleanliness, or through a too great readiness to interfere.

In an article\* in the present number of THE JOURNAL is the following:

"It seems strange that we are obliged to admit that puerperal wound infection in the ordinary daily prac-

\* Wiggin: Diagnosis, Prevention and Treatment of Puerperal Infection. Page 1005.

tice of physicians is of almost as frequent occurrence and is followed by as severe constitutional symptoms and with as high rate of mortality as it was fifty years ago. Many physicians have been slow to grasp the importance of the principles underlying modern surgical teaching or, while knowing these principles, they have yet failed to apply them to obstetric work and consequently have not profited by them. They are still too often seeking consolation and explanation of the fever and other constitutional symptoms complicating the puerperal convalescence, in the possibility that the disturbance arises from the beginning of lactation or from the specific poisons causing malarial or typhoid fever, instead of attributing those symptoms to their true cause, in almost every instance, wound infection."

Dr. Wiggin has given utterance to what is, unfortunately, too true. We are almost ready to make the statement even stronger than he has made it. We believe we are safe in saying that statistics, if carefully compiled, would show that in private practice the mortality from puerperal sepsis is greater to-day than in the pre-aseptic period. The great maternity hospitals, like the Rotunda at Dublin or the Maternity at Prague, show an astonishingly low death rate from this cause, and this in spite of the fact that students witness and assist at the deliveries and are permitted to make examinations. But it is this very fact of the striking reduction in the number of fatalities from puerperal fever in these great lying-in hospitals, where a few decades ago this dread disease destroyed so many lives, that has made physicians bold. Knowing that asepsis and antisepsis have wrought the marvelous change in the morbidity and mortality records in the hospitals, the physician feels that if he is aseptic in his work his record will be as good and he can do practically what he will. The old rule of "meddlesome midwifery is bad" is cast aside. With improved forceps of several patterns, with chloroform given with practically no danger, even the careful physician feels justified in early instrumental interference, resorts to version on slight provocation, is indifferent to lacerations because he can sew them up immediately, is digitally diligent in determining the progress of the labor; in fact, he hesitates at none of these because he has practically no fear of sepsis. And why? Because by his side is a bowl of bichlorid solution or of carbolic acid or of some other favorite antiseptic into which he dips his fingers, his silk, his forceps, perhaps, flattering himself that in this way he is rendering himself clean and protecting his patient from harm. We need not go into the details of how it all happens. There is a slip somewhere in the technique of his asepsis and the deed is done. The brush with which he cleans his hands may be foul, the towel soiled, or with clean hands he handles a chair or the patient's hand—in any one of a thousand ways he may commit an error that will account for the unfortunate result. And then, though he may have been scrupulously careful, an ig-

norant nurse may spoil it all with her dirty douche-point or her unclean hands.

These tragedies are occurring every day, and that, too, right in the midst of our large cities where are hospitals and medical schools in which the technique of surgical cleanliness is properly taught. It is time that the profession should wake up to the fact that an operation that is surgically unclean is often worse than no operation at all; that a careless obstetrician, overconfident because of his fancied protection by his so-called asepsis, may be a breeder of most serious mischief. The statement that the lying-in woman is aseptic is so true that the physician should enter upon the task of the delivery of such an one with as much caution and as much intelligent, painstaking preparation as in entering a surgically clean abdominal cavity. Most physicians are conscientious in these matters and the fault lies, when these mistakes occur, in some little slip in the aseptic measures or in a too great readiness to interfere, thus producing serious local damage that favors infection. The remedy lies in a clearer knowledge of the importance of details in asepsis and in a faithful observance of the same in every case.

#### INFORMAL PRESCRIBING AND ITS DANGERS.

Not infrequently a physician is tempted in the case of a friend or intimate acquaintance to give a therapeutic hint rather than a formal prescription. He may name some simple drug that can be taken with benefit. Sometimes the motive will be no more than the avoidance of prescription rates in the dispensing of the drug suggested. The longer a physician is in practice the less is he liable to make this mistake, for mistake it always is and one that may sometimes be followed by even serious consequences. Probably every physician of considerable experience has had occasion to regret such occurrences. No matter how apparently unmistakable word-of-mouth directions are, the non-medical mind can not be depended on to follow them as intended. People seem to abandon what appears the plain path of ordinary common sense at times on the presumption that they are following their physician's directions.

As a warning against this practice we have collected from recent literature some cases that show the serious evil that may flow from it. How easy it is, for instance, to suggest that a lotion of carbolic acid, 2 to 5 per cent. in strength, be used to wash off a small wound, or abraded surface, on a finger or toe. Suppose the patient, as is not unlikely, concludes that the use of a wet dressing, the gauze being soaked in the cleansing solution, may do good in preventing all danger of infection—a danger that the physician usually points out very clearly. The result may be gangrene of the finger or toe. Harrington<sup>1</sup> read a paper before the Massachusetts Medical Society in which he collected 132 cases of gangrene following the use of carbolic acid solutions, of from 1 to

1. Boston Med. and Surg. Jour., May 2, 1901.

5 per cent. strength. In not a few of these cases the solution was applied by the direction of a physician. Harrington himself has seen eighteen such cases in the Massachusetts general hospital and in most of them amputation of the finger or toe involved was rendered absolutely inevitable.

Effects almost as serious have followed off-hand therapeutic hints for purely medical affections. At a recent meeting of the Harvard Medical Society the case was reported of a matron who had taken some 150 drops of wintergreen oil within a few hours because her son-in-law, a physician, had suggested ten-drop occasional doses of this drug for certain presumably rheumatic pains from which she suffered from time to time. An extremely acute exacerbation of the painful condition led her to take the amount of the drug mentioned. Her medical relative-in-law found her cyanotic, extremely weak, almost pulseless and with sighing respiration. Experiences analogous to this are very common in the use of the coal-tar products for headaches, though the public has been very generally warned with regard to the possibilities of harm from these drugs and serious symptoms are not so frequent as they once were. Hints dropped as to the value of *nux vomica* for run-down conditions have often been followed by muscular twitchings and even more serious cramp-like effects because non-medical persons were convinced that if a little was good, a good deal must surely be better.

Serious results from the use of so well known a poison as arsenic are not often reported, but a case has been recently under observation. The patient suffering from psoriasis in a mild form was advised to take Fowler's solution in five-drop doses three times a day. He improved rapidly under the treatment. The following spring he suffered from a relapse of the psoriasis and of his own accord took Fowler's solution once more. This time it failed to relieve as promptly as before. The patient increased the dose until he was taking twelve drops three times a day. Acute symptoms of gastric disturbance developed that were not attributed to the arsenic. With the idea that the psoriasis was a manifestation of the disturbed general condition the arsenic was continued. Finally a physician was consulted, but only after all the ordinary remedies for gastro-enteritis had failed did the thought of possible poison occur. By this time an arsenic neuritis had developed and it is doubtful if the patient will ever be quite himself again. At least, he is not after a year of most careful treatment.

When a condition is serious enough to call for a physician's attention, the giving of a formal prescription is likely to prove least liable to subsequent inconvenience. It even seems better, as a rule, not to give many details as to the drugs that are being prescribed. Prejudices with regard to certain drugs exist and the negative suggestion thus brought into play may prove sufficient to counteract, to some extent at least, the effect of a special drug that otherwise would be helpful. Latin prescription writing has lost much of its mystery for the non-

medical, but it still remains a judicious means of maintaining a certain wholesome secrecy as to the drugs that are being employed. It is not that the physician fears that the abolition of this secrecy will in any way lessen his usefulness. Familiarity with drugs, however, is apt to bring them into undeserved contempt. The formality of the prescription remains the most trusty safeguard for patient as well as physician against such dangers as we have pointed out.

#### RARE COMPLICATIONS OF TYPHOID FEVER.

Numerous instances of the localization of the bacillus of typhoid fever in various parts of the body and consecutive suppurative processes have been recorded. There are not a few cases of typhoid abscess of the thyroid gland. Mastitis may occur in typhoid fever and, according to Thomas McRae<sup>1</sup>, it usually develops late in the disease, occurring with about equal frequency in both sexes, both breasts being involved in about one-half of the cases. In women the process does not seem associated in any special manner with active function of the gland. In a full report of a case of brain abscess in typhoid fever, due to the typhoid bacillus, McClintock<sup>2</sup> notes that in the literature he has found nineteen cases of meningitis, complicating typhoid fever, in all of which the bacillus was present, generally in pure culture; and five cases of brain abscess, in none of which the bacillus was found. The case described by McClintock may be said to be typical, the abscess—in the left temporal lobe—probably began to develop about the fifth week and led to death with basilar meningitis on the sixty-sixth day. A full study of the organism isolated leaves no doubt that it concerned a true *bacillus typhosus*.

The exact mechanism of these and similar, e. g., the osseous localizations of the typhoid bacillus is not clearly understood. Undoubtedly it is intimately associated with the distribution of the natural and acquired antibacterial substances in the blood. The importance of the so-called complement (alexin or cytase) in bactericidal action is now generally recognized and it is not difficult to believe that in infections this substance may be used up and disappear more or less completely from the serum. Metalnikoff and others report that in chronic suppuration and in the absorption of dead tissue the complements are diminished or absent; and Ehrlich and Morgenroth found that as the liver degenerates from phosphorus poisoning the complements disappear from the serum. Now it may be that when typhoid bacilli enter the blood they are drawn together into clumps by the agglutinins present, and thus lodged in a capillary loop they are hindered by the protective substances in the blood serum from further proliferation until by some accident or otherwise the complement is bound and used up by substances elsewhere in the body. The conditions seem too complex and too little understood to permit of any more definite explanation.

### THE NEXT ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The next annual meeting of the American Medical Association promises to be even better than that of last year. The indications are that the meeting will be much more largely attended and the programs promise a very high order of scientific work in the various sections. Last week we printed a list of the prominent hotels at Saratoga Springs, which of itself shows that that town will be able to take care of the Association in a most satisfactory manner. Besides the hotels indicated in that list, there are a large number of boarding houses and minor hotels, so that there can not possibly be any doubt that ample accommodations will be provided for all who attend the session. As regards prices, like all fashionable resorts where the hotels are open only part of the year, the prices of some will be high enough to satisfy the most fastidious; but on the other hand, there are plenty of good hotels and boarding houses having rates within the reach of all. While the railroad rates have not been announced, the Committee on Transportation believes that it will secure one-half rates on some of the roads at least, if not on most of them. This, however, has not yet been promised.

### TWO MORE COLLEGES COMBINE.

One of the conditions often complained of in this country is the large number of medical colleges and the consequent unnecessary output of medical graduates each year. One of the good signs of the times is the fact that the evil is remedying itself gradually and surely. We recently noted the fact that the colleges in Ohio, especially in Cincinnati and Cleveland, were considering the advisability of combining. Some combination of colleges in Kansas City is also talked of, but it is only talk thus far. According to a circular just received, the two regular schools of Denver, viz., Gross Medical College and the Denver College of Medicine, have just combined, the name of the new school to be the Denver-Gross College of Medicine. It will be the medical department of the University of Denver. Each of the old schools agree to turn over to the new one all its furniture, apparatus, instruments, charts, etc., free of all incumbrances. The business affairs will be in the hands of a board of trustees composed of nine members made up of those connected with the old schools. The faculty of the combined school is a large one and takes in practically all the men who were connected with the old faculties. This will make the Denver-Gross College of Medicine one of the strongest in the West.

### NURSES AND MATRIMONY.

The industry of nursing is apparently a captivating one to young women, but it has its drawbacks. It appears that the future nurse must be a celibate. There is said to be a decided tendency among hospital physicians and matrons in London at the present time to discourage the offers of services on the part of engaged young women or those who are likely to include matrimony in their life plans. It is also said that some are suspected of utilizing their opportunities to inveigle medical men and those prospectively such into pedo-

trophic partnerships, the nursing course being only a means to the end. It seems a pity that those who are as well suited to make and adorn a home for a deserving man, as are many of the nursing profession, should be debarred from the privilege, the more so when we consider how well adapted their training will make them for such function, but it seems to be the trend of the times. This, of course, is not speaking of the nurse adventuress who is an occasional and deplorable fact; her case is another story. Perhaps with the multiplication of training schools, which is the order of the day, there will be found a way out, or provisions may be made for a special premarital education in nursing, in which no vows, given or implied, will be required. The philanthropic young woman can then work out her destiny without let or hindrance.

### FRAUDULENT USE OF ANOTHER'S FAME.

A decidedly bold fraud has been perpetrated upon a Chicago surgeon by the insertion of the following advertisement in the *Kansas City Journal*:

"Patients Notice! Always ask Cancer or Tumor Specialists to show their State Board of Health License before taking treatment. If not licensed they can not cure you. Cancer can not be cured by needle injection, plaster or any other way but by Dr. John B. Murphy's System. Address 16 State St., Chicago." It will be noted that the surgeon's name is vaguely used to explain the supposed method of the fakir and his opinion of other means of cure. The fact that there is no such system is not known by the general public, who may readily suppose that such a well-known surgeon has a method of his own for every important disease. The nomenclature of operations and systems of treatment is a medical topic foreign to the general public, and the shrewd wording leads the careless reader to infer that the famous surgeon is to be addressed. Evidence of this effect is forthcoming in the mail addressed to him from those desiring treatment. The author of this advertisement got himself into the reach of the law by ordering a change of address from 16 State street—a saloon which is apparently innocent as far as this particular offense is concerned—to a so-called "Red Cross Hospital" in the disreputable West Madison street district. The forged signature of Dr. Murphy on this order would have passed on a check, we are informed.

### SURGEON-GENERAL STERNBERG.

The Secretary of War has transmitted to Congress a recommendation that Surgeon-General Sternberg, when his active service is legally terminated next June, be retired with the rank of Major-General. This is endorsed by General Corbin, Adjutant-General of the Army, and with it is communicated a biographical sketch of Dr. Sternberg with a list of his leading contributions to medicine up to 1893. This naturally does not include some of Dr. Sternberg's best work, but it makes a showing that ought to convince congressmen that in thus advancing him a grade they are honoring one who has been an honor to his country as well as a faithful public servant for forty-one years, much of the time in arduous and perilous service in the field and on the frontier.

Indeed, we can say, without disparagement of any of his predecessors, that as a scientific medical man he has exalted the office of surgeon-general of the United States Army and that at the present time we are not aware that such a position is anywhere held by anyone of superior or even equal scientific reputation as an original investigator and authority. If, as General Corbin says, the Surgeon-General of the Navy was entitled by law to be retired with a rank equivalent to that of major-general, by what rule of justice can not the like officer of the Army with a wider range of work and greater responsibilities be retired with the same rank and emoluments? Dr. Sternberg's record is well known to the members of the medical profession, which has shown its appreciation by his election to many honorable positions and honorary memberships both here and abroad. The members of Congress can be assured that by the legislation requested they only carry out the wishes of the class of their constituents both in and out of the medical profession who can best judge of the propriety and need of such action. It is to be hoped that the recommendation will be promptly followed and the act made effective before the time of Surgeon-General Sternberg's retirement.

#### TUBERCLE BACILLI IN CHEESE.

During recent years much study has been given to the subject of tubercle bacilli in dairy products, especially milk and butter. This study has been in a large measure instrumental in bringing to notice a group of bacilli, which are acid-proof, like the tubercle bacillus, but which differ from it in other ways. It is not improbable that these bacteria have been sometimes mistaken for the tubercle bacillus in milk and butter; this mistake could occur the more readily if the identification of the tubercle bacillus was mainly dependent upon its staining properties. Still there is little doubt but that true tubercle bacilli are found in all of these dairy products, and that they may become a real danger when taken into the bodies of predisposed individuals. The recent agitation regarding the relation of human and bovine tubercle bacilli has not materially altered the views, previously held by competent medical men and investigators, that tubercle bacilli in dairy products may produce infection in man. If tubercle bacilli are found in milk, they are naturally also present in cheese. Experiments were made in Switzerland over two years ago, to determine the fate of tubercle bacilli in cheese, and it was demonstrated that they died out between the thirty-third and fortieth day in cheese made after the Emmenthaler method, but considerably later in cheese made approximately after the Cheddar method. The experiments regarding the time that tubercle bacilli would remain alive in Cheddar cheese, which is made in the approved manner, have been repeated by F. C. Harrison.<sup>1</sup> An emulsion of tubercle bacilli was added to milk at the same time as the rennet, and cheese was made from the milk in the manner required to obtain typical Cheddar cheese. After various lengths of time, guinea-pigs were inoculated with portions of the cheese and it was found that the tubercle bacilli died out somewhere between the

sixty-second and seventieth days. Even some time before this, the number of tubercle bacilli was small or else they were much reduced in virulence, for the guinea-pigs inoculated on the forty-second and fifty-second days were all lightly infected. Harrison concludes that these experiments justify the statement that Cheddar cheese contains no living tubercle bacilli, that might naturally be present, when it is ten weeks old; and hence no danger need be apprehended from eating living tubercle bacilli in Cheddar cheese.

### Medical News.

#### ALABAMA.

**New Hospital at Montgomery.**—Ground was broken, April 2, for the new hospital of the Sisters of Charity at Montgomery, to cost \$100,000.

**Birmingham Medical College.**—At the graduating exercises of this college, March 28, Dr. Benjamin L. Wyman, dean of the college, conferred degrees on a class of 8, and Hon. John M. Caldwell, Anniston, delivered the address to the graduating class.

**Medical College of Alabama.**—The forty-third annual commencement of this institution was held in Mobile, April 8. A class of 13 received diplomas from the dean, Dr. George A. Ketchum. The address was delivered by Prof. Julius Tutwiler Wright, Mobile, who chose for his subject "Criminology."

**New Hillman Hospital.**—The arrangements for the erection of the New Hillman Hospital, Birmingham, are nearly completed. The association has already \$33,000 in hand toward the \$50,000 which will be required for the construction of the building. The Birmingham Medical College will erect its new building to cost about \$40,000 on the lot next to the hospital.

#### CALIFORNIA.

**Oakland Medical College.**—Ground was broken, March 31, for the new building for the Oakland College of Medicine and Surgery. The building is to cost about \$15,000.

**San Francisco Board of Health.**—After injunctions, counter-injunctions and threatenings, the old and the new city boards of health are now resting and awaiting further legal developments.

**Medical Electrician Acquitted.**—A medical electrician of Los Angeles, arrested on the charge of practicing medicine without a license, was acquitted by a jury, April 3. Her sole defense was that she acted under the instructions of a regularly qualified physician.

**Physicians Refuse to Pay Local License Fee.**—Ten of the thirteen practicing physicians in Chico were arrested, March 31, for refusal to pay the city license. Under an ordinance of Chico physicians are required to pay \$5 per quarter license. This ordinance has been in effect since 1897, and until this time the license has been paid. Now the physicians have decided to test the ordinance and have organized for that purpose.

#### ILLINOIS.

**Insane Transferred.**—Watertown hospital has transferred 20 male and 30 female incurably insane patients to the new state institution at Bartonville, near Peoria.

**Raising Funds.**—The Julia F. Burnham hospital board, Champaign, has already raised \$11,500 of the \$15,000 required to obtain \$5000 conditionally offered by William B. McKinley.

**Railway Hospital at Decatur.**—The Wabash Hospital Association has accepted the offer of the citizens of Decatur of a site for the Middle Division Hospital. Plans have been prepared and a building to cost \$50,000 will be erected.

#### Chicago.

**Dunning to Bartonville.**—The superintendent of Cook County Insane Asylum has transferred 65 incurable women to the Hospital for the Incurable Insane.

**Air-Borne Diseases Rife.**—All the air-borne diseases are again as rife as before the March rains, and the high winds and dry surfaces give little present hope of relief.

**Increased Mortality.**—As compared with the week previous the Department of Health reports an increased mortality last

1. *Cent. f. Bakt., Abteilung 1*, March 3, 1902, 250.

week from all the chief causes of death except scarlet fever, pneumonia and violence. The 562 deaths represent an annual rate of 16.10 per 1000 of population, as against 14.19 and 13.8 respectively for the previous week and the corresponding week of 1901, or more than one-seventh and more than one-fifth increase respectively.

**Eye and Ear Hospital Internes.**—The annual examination for internes for the Illinois Charitable Eye and Ear Infirmary will be held at the infirmary, 227 W. Adams Street, Chicago, commencing at 2 p. m., Monday, April 28, and continuing April 29 at 1 p. m. The number of positions to be filled is three, and the length of service is one year. This examination is open to any practitioner of medicine or graduate of any recognized medical college.

**Vaccination in Zion.**—Frightened either by the presence of smallpox in Zion College or by the bill of expense he will have to meet, Dowie has issued an order "allowing" his subjects to be vaccinated. Dowie will have to meet a bill of expense when the epidemic is over. He will have to pay \$25 a week for the care of each patient at the Isolation Hospital, and besides he will have to pay \$3 a day for the services of four city policemen who have been enforcing the quarantine.

**Chicago Lying-In Hospital Report.**—The annual report of this hospital shows that during the last year 1082 patients were attended, 142 of whom were confined at the hospital and more than 11,000 visits were made. During the last four years not a single maternal death occurred in the out-service. The incubator ward had 13 inmates, of whom 10 survived. The school for nurses trained 63 nurses in obstetrics during the year. The medical board now includes Dr. Joseph B. De Lee, representing the Northwestern University Medical School, Dr. J. Clarence Webster, representing Rush, and Dr. Frank B. Earle, representing the College of Physicians and Surgeons.

**The Officer-of-the-Day Recommends.**—The medical officers-of-the-day recently established at Cook County Hospital have made from day to day the following recommendations: 1. That the number of visitors to the hospital be restricted. 2. That a convalescent home be established. 3. That rollers be placed on all beds in the hospital. 4. That closer watch be kept to prevent smuggling of liquor to patients. 5. That convalescents be permitted to have more out-door recreation. 6. That out-door exercise and tennis be prescribed for internes and nurses. 7. That a dressing-room be provided for non-septic patients. 8. That female patients be permitted to visit the lawn. 9. That the wards and beds be constantly painted.

#### IOWA.

**Mercy Hospital Bequest.**—By the will of Michael Hennessy of Dubuque, \$50,000 is bequeathed to Mercy Hospital in that city.

**Hospital for Iowa Falls.**—Initial steps have been taken toward the establishment of a hospital in Iowa Falls. A site has been secured at a cost of \$4500, of which one of the owners donated \$1500. Plans have been prepared for the building which, when equipped, will cost between \$18,000 and \$20,000. Toward this expense \$6000 has already been secured.

**Osteopaths Recognized.**—The Iowa house has passed the senate bill in recognition of the osteopathic school of physicians, authorizing the State Board of Medical Examiners to issue certificates to graduates of osteopathic colleges and to others who pass examination, and authorizing the choice by the governor of an osteopath to become a member of the State Board of Health and State Board of Medical Examiners.

#### KENTUCKY.

**Gift to Lexington Hospital.**—James R. Keene has given \$1000 to the Good Samaritan Hospital, Lexington.

**Dr. Byrne Acquitted.**—Dr. W. A. Byrne, Peak's Mill, Franklin County, was acquitted in the County Court, April 4, of the charge of violating the statutes regarding medical practice. Dr. J. N. McCormack, of the State Board, concurred.

**Louisville National Medical College** held its fourteenth annual commencement, April 7. Degrees were conferred on a class of 7. The address to the graduating class was delivered by Augustus E. Wilson, and the alumni address by Dr. Pickett of the class of 1898.

**Certificate Sufficient Qualification.**—Dr. Joseph M. Matthews, president of the State Board of Health, and City Health Officer M. K. Allen have furnished the secretary of the sinking fund a certified copy of the list of physicians in Louisville

who are qualified to practice medicine under the state law. Hereafter he will accept the certified copy of the list as prima facie evidence that the license should be issued and will issue the license to those on the list without the necessity of bringing the personal certificate to the sinking fund office.

**Addition to Norton Infirmary.**—An addition to the John N. Norton Memorial Infirmary, Louisville, has just been completed, which more than doubles its capacity, the new and commodious operating rooms in the new building giving facilities for surgical work equal to any institution in the Southwest. The old building which has done so much good work in the past twenty years is being renovated and new steam heating apparatus and electric light fixtures installed so that when completed the entire plant will be as modern as it is possible to make it. In opening the new infirmary the trustees have followed the example of like institutions in other cities and determined upon a reorganization, electing a medical and surgical staff, feeling the need of the constant supervision and advice of professional experts who are thus made responsible for the conduct of the house. It is emphasized, however, that the infirmary will continue to welcome any and every patient brought to its doors by a reputable physician, to be under his own particular care, without intrusion from any one, and there will be no interference on the part of the medical staff with the patient of any physician. The members of the medical staff are as follows: Surgery, Drs. A. M. Cartledge, W. O. Roberts, E. L. Pearce, James B. Bullitt, and Louis Frank; internal medicine: Drs. J. B. Marvin, John G. Cecil, F. W. Koehler, C. W. Kelly and F. C. Simpson; obstetrics and diseases of children: Drs. H. B. Ritter and Henry E. Tuley; ophthalmology: Drs. S. G. Dabney and A. O. Pfingst; dermatology: Drs. I. N. Bloom and H. H. Koehler; pathology: Dr. J. A. Flexner. In rearranging the building, the administrative portion has been removed to the first floor of the new addition, with an electric elevator leading to each floor; the operative rooms are located on the fourth floor with dressing rooms on each floor; a new drug room will be installed with added facilities for obstetric work. The institution has a private laundry plant with latest machinery and in every department is thoroughly up to date.

#### MARYLAND.

**Medical Assistant Authorized.**—The legislature has passed a bill allowing a medical assistant to the secretary of the State Board of Health.

**Personal.**—Dr. Louise Erich has been elected professor of orthopedics at the Woman's Medical College, Baltimore.—Dr. Howard Bratton, Elkton, has been appointed health officer of Cecil County.

**Alumni Address.**—The address before the Alumni Association of the University of Maryland School of Medicine, May 2, will be delivered by the Hon. Joshua W. Hering, M.D. (class of 1855), state comptroller.

**Infectious Hospital Suit.**—As a result of the failure of the Baltimore city council to confirm the purchase of a site for the Infectious Diseases Hospital by the hospital commission, suit has been brought against the city by the owner of the land in dispute for \$20,000.

**The Union Protestant Infirmary,** Baltimore, will be reopened in a few days. It is practically a new building. A large addition has been made, and the whole thoroughly modernized. Three houses north of the main building have been purchased for the use of the 30 nurses. There are now 100 beds. The operating room is on the fourth floor. One feature of this is a cabinet where salt solutions are kept at blood-heat for immediate use. In the children's ward the doorknobs are placed high so that a child can not reach them. The floor of this ward is of compressed cork, therefore always warm so that children may sit on it without catching cold, and falls are not felt as much as on plain wooden floors. Around the walls for 3½ feet is white tiling, one course of which has Mother Goose pictures in blue. Children are first received in a special department, where they are bathed and in all infectious cases the clothing is fumigated. There are also isolation rooms, one for delirious patients and a lounging room. All the doorknobs are of white glass and the painting white enamel. The lighting is by electricity. The private apartments on the second and third floors are furnished with iron bedsteads enameled in white and with birdseye maple furniture. Dr. J. S. Davis, Jr., is resident physician, and Drs. W. A. Fisher, George S. Drake and William M. Dabney are assistants.

## NEBRASKA.

**Creighton Feasts and Will Dance.**—Creighton Medical Society, composed of undergraduates of Creighton Medical College, Omaha, held its annual banquet, April 16, and will give its first annual ball, April 23.

**University Absorbs College.**—As a result of an important meeting of the board of regents of the State University, April 9, Omaha requires a direct and local interest in the university. A contract was adopted which affiliates the Omaha Medical College with the university by virtually annexing it. The medical course will be four years—two of which are to be spent in the university at Lincoln and the remaining two years in the Omaha college. A university degree will be given.

## NEW JERSEY.

**Practicing at 93.**—Dr. Otis R. Freeman, Freehold, although in his ninety-third years, is still in the active practice of medicine.

**Woman's Hospital Bequest.**—By the will of the late Justis B. Crandol, Seaville, \$5000 is bequeathed to the Woman's Hospital, Philadelphia.

**Dr. Lemuel G. Goode,** Jersey City, who recently underwent an operation for the amputation of his leg, has recovered and taken up his practice.

**Sanatorium for Tuberculosis.**—Through the efforts of the governor, the legislature passed the bill appropriating \$50,000 for the establishment of a state sanatorium for consumptives.

**Oldest Alumnus of Princeton.**—Dr. James Curtis Hepburn, Orange, a graduate of Princeton in 1843 and of the University of Pennsylvania Medical Department, 1836, celebrated his 87th birthday recently. He has spent 37 years as a medical missionary in China and Japan.

## NEW YORK.

**Suit Against Lunacy Examiners.**—The wife of a wholesale liquor dealer, who was adjudged insane in 1898 and was subsequently discharged because a sheriff's jury declared that she was sane, has begun suit for \$100,000 damages against Drs. Allen Fitch and Austin Flint, examiners, and Dr. O. J. Wilsey, superintendent of the Long Island Home at Amityville.

## New York City.

**Dr. William Aldren Turner,** of London, was the guest of the New York Neurological Society at its meeting April 8. He presented an interesting paper entitled "An Experimental Study of the Reflexes in Total Transverse Lesions of the Spinal Cord."

**City Aid for Private Charities.**—The new Comptroller has announced a sweeping reform in the matter of aiding to support hospitals and other charitable institutions. The city now pays annually \$2,750,000 to these institutions and in some instances nearly all of the income comes from the city. It is now proposed that the city shall contribute only as much to these institutions as they are able to obtain from private sources.

**Abattoirs Declared a Nuisance.**—A number of property holders and residents in the vicinity of the slaughter houses located near the East River and Forty-second street, many of them women, having become exasperated by the vile odors that make their life miserable in the summer, have organized themselves into the Citizens' Health Protective Association, and purpose to oust the abattoirs that have so long been a nuisance in this region.

**Bellevue Out-Door Department to Close.**—It is announced that the trustees of the city hospitals have decided to close, on June 1, that old and justly celebrated dispensary known as the "Bellevue Out-Door Poor." The trustees declare that they need this building for dormitories and that adequate provision for the patients is made at the nearby medical schools of Cornell and the New York University; but there are some who know the sharp rivalry between the medical schools who are disposed to think that Bellevue has been betrayed into the hands of these rivals.

## Buffalo.

**Ambulance for German Hospital.**—The German Hospital has received a new and beautiful ambulance and is now prepared to answer emergency calls.

**Correction.**—Dr. Livingston L. Lewis, Hoboken, desires us to announce that it was not he, but Dr. Harry Lewis, North Bergen, who was married to Mrs. Gus Atkins of North Bergen, March 20.

**Accommodation Inadequate.**—In view of the fact that the children's wards and nurses' quarters have become inadequate at the Erie County Hospital, it is proposed to build a children's pavilion and to convert the children's ward for nurses' quarters.

**Eddyites Agree to Report All Communicable Diseases.**—The Health Commissioner has persuaded the local Eddyites to report all contagious diseases and to submit such cases to quarantine. By this treaty the Health Department gives much more recognition to the Eddyites than they deserve, for it practically licenses them as practitioners and therein lies the danger. As the Buffalo News says editorially, "they are good diplomats, these people who deny disease and get rid of every undesirable thing in life—and death—by simply explaining it away."

## PENNSYLVANIA.

**Dead-Beat List.**—The Lawrence County Medical Society has determined to establish a "dead-beat" list and has appointed Dr. James M. Popp, New Castle, collector.

**Joseph J. Kinyoun, M.D., Ph.D.,** late surgeon of the United States Marine-Hospital Service and director of the Hygienic Laboratory at Washington, has assumed the directorship of the biologic laboratories of the H. K. Mulford Company, Glenolden.

**St. Francis Hospital, Pittsburg.**—At the annual meeting of this hospital April 9, it was reported that 1628 patients had been cared for during the year; that the training school for nurses was giving excellent satisfaction and that the hospital was in prosperous condition.

**Personal.**—Dr. James L. Srodes, Wilkinsburg, moved to Woodville, April 1, to become the medical superintendent of the Allegheny County Home.—Dr. Cyrus B. King, Allegheny, has been appointed a member of the State Board of Charities.—Dr. C. E. Lockwood, Brackney, has purchased the practice of Dr. Frank I. Smith, Hallstead.—Drs. John Rourke and Robert E. Culler, internes at the Reading Hospital, have been re-appointed.—Dr. John W. Gordon, Belle Vernon, a member of the Fayette County pension board, has resigned; Dr. Jacob S. Hackney, Uniontown, succeeds him.—Dr. Thomas L. White, McKeesport, sailed for Europe, April 10.—Dr. Andrew H. Elliott, Emsworth, has been compelled to move to Colorado for his health.—Dr. Gustav T. Fox, Bath, has resumed practice after a prolonged vacation.

## TENNESSEE.

**The West Tennessee Medical and Surgical Association** will hold its annual meeting at Jackson, May 22 and 23, under the presidency of Dr. Jere L. Crook, Jackson.

**State Board of Health.**—At the annual meeting of this body in Nashville, Dr. William J. McMurray, Nashville, was elected president and Dr. Heber Jones, Memphis, vice-president.

**Funds for Erlanger Hospital.**—The County Court, on April 8, appropriated \$5000 for the support of Erlanger Hospital, Chattanooga, the expense to be borne equally by the city and county. The court also appropriated \$7500 for an addition to the County Insane Asylum.

**Faculty Changes.**—University of Nashville Medical Department announces the following faculty changes: Dr. Alberto Hudson, from adjunct professor to professor of anatomy, vice Prof. Carl C. Warden, resigned; Dr. Samuel M. Bloomstein, professor of diseases of children; Dr. Holland M. Tigert, assistant to the chair of materia medica and therapeutics, vice Dr. Robert S. White, resigned; Dr. Adam G. Nichol, director of the surgical laboratory, and Dr. James Whitworth, first assistant demonstrator of anatomy and lecturer on regional anatomy.

**Commencements.**—The fifty-first annual commencement exercises of the Medical Department of the University of Nashville were held March 27. Chancellor James D. Porter presided and conferred degrees on a class of 34. Prof. Hill McAlister delivered the faculty address.—The Medical Department of the University of Tennessee, Nashville, held its graduating exercises, April 3, at which Col. J. B. Killebrew, representing Dr. Charles W. Dabney, conferred degrees on a class of 17. Dr. Robert O. Tucker delivered the charges to the graduating class, and Dr. Paul F. Eve, dean of the faculty, presented the diplomas.—Vanderbilt University Medical Department, Nashville, graduated a class of 16, April 3. Dr. N. Pendleton Dandridge, Cincinnati, delivered the address to the graduating class; Dr. W. Frank Glenn gave the faculty address, and Chancellor Kirkland conferred the degrees.

## GENERAL.

**Cholera Increases in Manila.**—The Philippine Islands have had 663 cases of cholera reported thus far and 510 deaths. Of these, 245 cases and 192 deaths were in Manila.

**Death of Dr. Meacham.**—Dr. Franklin A. Meacham, major and surgeon, U. S. A., assistant to Major Maus, health commissioner of the Philippines, died, April 15, at Manila, from overwork in the cholera supervision.

**Internes Wanted in New York Hospitals.**—Students about to graduate who are unable to secure positions in general hospitals, or young physicians whose terms are about to expire in general hospitals and who wish to enlarge their experience, are now offered an opportunity to enter the New York State Hospitals as internes or clinical assistants. These positions provide lodging and board. Appointments are made for a year. Some 28 positions will be opened in the 14 hospitals situated in the following places in New York State: Utica, Ward's Island in New York City (two hospitals), Buffalo, Gowanda (homeopathic), Rochester, Binghamton, Ogdensburg, Kings Park, L. I., Poughkeepsie, Flatbush (Brooklyn), Willard, Central Islip, L. I., and Middletown (homeopathic). Although these are hospitals for the insane, yet they are so large that opportunities for experience in general medicine are abundant. Each hospital is well equipped, the field for study in general medicine is excellent and surgical operations of all kinds are frequently performed. Many students will be glad to learn that positions of this kind have been thrown open to them. It is believed that young physicians wishing hospital experience will profit by a year's residence in one of these hospitals, and such as desire to continue in special work would be eligible for appointments subsequently to salaried positions in the same service. No examinations will be necessary, but application must be made in person with good references, directly to the medical superintendent of any of the above named hospitals or to Dr. Frederick Peterson, President of the Commission in Lunacy, 4 West 50th St., New York City.

**Measles Among Troops in Philippines.**—The report of the chief surgeon, Division of the Philippines, dated Feb. 15, 1902, has been received at the surgeon general's office. The percentage of sick for the month of January 15 to February 15 was 6.39. The total number of cases reported was 2611 in a mean strength of 40,820 men. There were 230 cases of venereal diseases, 118 of wounds and injuries, 124 of malaria, 112 of dysentery, 69 of diarrhea and 25 of other intestinal diseases. The deaths numbered 54, as compared with 59 during the previous month. Two men were killed in action, 2 died of battle wounds, 2 of gunshot wounds not received in action, 14 of dysentery and 5 by drowning. Four hundred and twelve medical officers were on duty in the division during the month, with 2165 men belonging to the Hospital Corps, and 67 female nurses belonging to the Army Nurse Corps. Bubonic plague, to date, had not appeared among the troops, and only one case was reported for the month in the whole archipelago. This occurred on the person of a native woman, on February 9, in the walled city. She died soon after discovery. The inhabitants of the house were removed to the detention camp of the Board of Health, where they were inoculated with Kitasato's serum and Shiga's vaccine matter. To date no further cases had occurred. The board detailed for the investigation of Surra had not made a report, but it is understood that during their trip through Southern Luzon they found a great number of cases of the disease. The transport *Sheridan* brought measles to Manila on January 26. On February 5 the first case of this disease was developed. Notwithstanding careful isolation, disinfection and inspection, 22 other cases followed, all of which were isolated at the First Reserve Hospital. The troops, including the 27th Infantry, 11th cavalry and casuals were taken to Mariveles on the *Sheridan*, their clothing and everything which had been exposed were disinfected, and they returned on the *Relief* to Manila. The *Sheridan* was brought back to the city and unloaded; she was then turned over to the quarantine officer for thorough disinfection. The men of the 27th Infantry were put in a detention camp at Camp Wallace, the 11th Cavalry at Pasay, and the casuals at Santa Mesa. No further cases occurred except at the last-mentioned point, where several children who came on the *Sheridan* were attacked. Some of them are still in the city, and a few other children have been infected by them. The troops free from the disease have been released from the detention camp. The cases were of a mild type, as measles usually is in this climate.

**Health and Sanitation in Manila.**—The report of the Commissioner of Public Health, Major L. M. Maus, surgeon,

U. S. Army, for the month of January, 1902, states that the deaths in Manila for the month were equal to an annual rate of 30.33 per thousand, as compared with 30.12 in January, 1901. It is to be observed, however, that the former rate was computed on a basis of 297,154 inhabitants, while the latter was calculated from a population of 250,000. Neither of these estimates of the population appears to be more than guesswork. Among the permanent residents of the city there were 765 deaths and 87 among the transients. The former list was made up of: Filipinos, 723; Chinese, 25; Americans, 3; U. S. Soldiers, 5; all others, 9. As usual, the greatest mortality was due to infantile convulsions, there having been 248 deaths from this cause alone. Other prominent causes were: Diarrhea and dysentery, 99; tuberculosis of the lungs, 44; non-puerperal eclampsia, 37; acute and chronic bronchitis, 47; beri-beri, 32; meningitis, 21; intermittent fever, 20; senile debility, 16. Not a case of smallpox, scarlet fever or diphtheria was reported during the month. The birth rate is stated as 14.59 per thousand, the absolute number having been 368. Until many radical sanitary defects and conditions are removed or remedied the mortality among the lower classes will remain larger than it should be. The principal improvements needed are: 1, the installation of a modern sewerage system; 2, the construction of filter beds and an increase in the city water supply; 3, walling and cleaning of the esteros, a number of which should be closed; 4, remodeling or removal of the majority of the old stone buildings in the city; 5, obliteration of the moat around the Walled City and removal of the wall; 6, raising the streets and city site; 7, repairing and widening the streets; 8, constructing a good system of gutters and subsoil drainage, and 9— but not least—providing suitable parks.

No plague occurred in the city during the month, the last case having been reported Dec. 24, 1901. During January, 1900, 18 cases occurred and in January of last year 4; but in May of that year there were 124 cases. Radical measures for the suppression of the disease are being enforced by the Board of Health, among which may be mentioned the cleaning out and disinfection of all houses in which plague cases have occurred or in which rats affected with the disease have been found; the destruction of rats by means of traps and poison; the immunization of the lower classes, among whom the disease usually occurs, by means of the Shiga vaccine; the thorough cleaning and disinfection of all the filthy habitations in the city and the prevention of overcrowding. Since September, 1901, 33,772 rats have been caught, of which number 30,786 were examined in the laboratory. Of this number 229, or 0.7 per cent., were found to be infected. During January, 1902, 16,776 were examined, 51 of which, or 0.3 per cent., were infected. It would appear from this that the disease among rats is gradually disappearing.

Boards of Health have been organized in nineteen of the provinces, and municipal boards are being established in many of the pueblos. These boards will prove of great benefit to the Philippines, not only in improving the sanitary condition of the natives, but in the suppression of smallpox and of epidemic diseases among domestic animals as well. All the presidents of provincial boards have been provided with the necessary instruments for immunizing cattle against rinderpest. From the Vaccine Institute in Manila there were issued during the month 109,075 units of vaccine virus to the various provinces for the use of the natives.

**Smallpox.**

**Alabama:** Several new cases of smallpox in mild form are reported near Larkinsville, Jackson County.

**California:** The report of the quarantine committee at Randsburg shows that 2 patients remain at the pesthouse; 71 male patients and 10 females have been under treatment at the isolation hospital, and 30 have been quarantined.—At Lewiston, five new cases are reported in one family.

**Illinois:** The Chicago Department of Health announces that of the 16 new cases of smallpox discovered and removed to the isolation hospital last week one was imported from Iowa and one from Springfield, Ill.; five others were cases contracted from exposure at Zion College, discovered March 26. At the close of the week 42 cases remained under treatment in the hospital, 10 had been discharged, recovered, and no death had occurred. Since January 1 there have been 128 cases treated, with one death and 84 recoveries.

**Maryland:** At the monthly meeting of the State Board of Health, April 9, eight cases were reported in the counties outside of Baltimore, viz.: 2 each in Wicomico, Caroline and Allegheny; 1 each in Talbot and Worcester, 8 in all. Since March 1, there have been altogether in these counties and in Somers-

set, Frederick and Howard 26 cases, of whom 2 have died.

Massachusetts: A short time ago Dr. Morse, of the State Board of Health, made the announcement that there had been 46 cases of smallpox in Gilbertville, and six in Ware during the last three months. This was doubted by the majority of the people, and even by some of the local physicians. Since that time two more cases have occurred which the patients' friends refused to believe to be smallpox. The board finally decided to get a specialist, and Dr. Thomas B. Shea of Boston was called in. He examined the patients carefully and pronounced the disease smallpox.

New York: Health Commissioner Lederle of New York City has asked the Board of Estimate and Apportionment for a bond issue of \$1,025,000 to enable better provision to be made for smallpox cases in Greater New York. As an example of the inadequacy of the present arrangement, it is stated that cases of smallpox having developed in a remote portion of the Borough of Richmond, the diagnostician of the health department was forced to travel 40 miles; the ambulance sent for the patients went 36 miles; the boat for contagious diseases made a trip of 66 miles, and it was fifteen hours after the nature of the disease had been certified before the patients could be conveyed 33 miles to the nearest hospital. Evidently there are unusual difficulties attending the proper administration of the health department in this second "city of magnificent distances."

Ohio: Scio has 6 well-developed cases of the disease.—Shelby has had a return of the disease and seven houses are quarantined.

South Dakota: The commissioners of Lawrence County have passed a resolution making vaccination compulsory, hoping in that way to relieve the epidemic of smallpox that has been raging in the Black Hills. The Board of Health has recently fumigated all saloons in Deadwood, and strict quarantine regulations are being enforced. Under the resolution just adopted all persons who have not been vaccinated within the last year must submit to the operation. Those who have not the money to pay for it may have it done free of charge by the county physician.

Virginia: Smallpox still prevails to a greater or lesser extent in many of the counties. In some sections—counties contiguous to those in which the disease is reported—there are no reports, making it impossible for the secretary of the board, Dr. Paulus A. Irving, to definitely determine the actual conditions in the state. Alleghany county has 1 case; Augusta, 8; Bedford, 4; Botetourt, some; Floyd, several; Fluvanna, 60; Franklin, 50; Gloucester, 30; Isle of Wight, 1; Northampton, 1; Patrick, several; Pittsylvania, 40; Roanoke, 1; Rockbridge, 4; Wise, some, and Wytthe, 12.

Canada: Halifax, N. S., has been declared free of smallpox.—Manitoba, which, after a long siege of smallpox, was nearly empty of patients, is again full. The disease has broken out afresh in different sections of the city and fears are entertained of an epidemic. It is stated that returning lumbermen from the camps which have broken up are the source of the infection. The medical health officer, Dr. Douglass, is putting forth strenuous efforts to hold the outbreak in check.—In 1901 there were 1879 cases throughout Ontario. In January, 1902, 629 cases were reported; in February, 707; in March, 302. The cases have therefore fallen off over fifty per cent. in the last month. The total number of cases reported during the past fifteen months amounted to 3517.—Official records show that the present outbreak of smallpox in the city of Quebec dates from October 28 last. Since that time there have been 671 cases, and the largest number of cases on the books of the health authorities at any one time was eighty-two. In that time there have been only eight deaths, so light has been the character of the disease. The assertion has been made by doctors and others in the city that there were several hundred cases of smallpox in the city, unknown to the health authorities, and that people were constantly exposing themselves to the disease in order to take it and thus avoid vaccination. This is owing to the mildness of the disease.

#### CANADA.

Dr. W. H. Drummond, Montreal, known as the "habitant" poet-doctor, is to receive distinct honor from Toronto University at its June convocation. On that occasion he will receive the degree of Doctor of Laws.

Vancouver Personal.—Dr. Robertson of Vancouver has sailed as ship's surgeon on the *Aorangi* and will make the round trip to Australia. The regularly appointed surgeon had arrived too late to accompany the steamer to Vancouver on its last voyage.

The Rhodes' Scholarships are of the yearly value of £300 each and are tenable at any college in the University of Oxford for three successive academic years. Ontario will have three, Quebec three and Newfoundland three. It is expected that the other provinces of Canada will be provided for later by the executors.

St. John Medical Society.—After the regular meeting of this society on April 9, a complimentary dinner was given to Dr. Morris, one of its members, who has had charge of the smallpox outbreak at St. John, N. B. Mr. Ellis presided, and a very happy evening was spent by a large section of the medical fraternity of St. John.

The British Columbia Medical Society Council, once announced, is now amended. The result was so close that a recount was demanded, and Dr. Lefevre is declared elected in place of Dr. McKechnie of Nanaimo. The members are: For Victoria, J. C. Davie, O. M. Jones, C. J. Fagan (secretary); Vancouver, W. J. McGuigan, J. M. Lefevre; New Westminster, R. E. Walker; Kamloops, Arthur P. Proctor.

Canadian Association for the Prevention of Tuberculosis.—The annual meeting was held at Ottawa, April 17 and 18. An address by S. A. Knopf, M.D., New York, was entitled, "The Mission of Societies for the Prevention of Consumption in the Anti-Tuberculosis Crusade." The program covered all the avenues of effort in this important work and consisted largely of reports of committees of investigation with discussion of the same.

Changes at Toronto University.—The Senate of Toronto University has decided to separate the Board of Medical and Dental Studies. There will be hereafter three distinct boards, for medicine, dentistry and pharmacy. At the same meeting a statute amending the curriculum in medicine received its second reading. It provides that an examination and attendance in the fourth year will hereafter be necessary in ophthalmology, otology, laryngology and rhinology.

New Wing for Hotel Dieu Hospital, Montreal.—The Sisters of the Hotel Dieu, in charge of the Hotel Dieu Hospital, Montreal, have decided upon the erection of a large wing to the present hospital. The new wing will contain a new operating room and two special rooms for the use of the x-ray. The remainder of the wing will be divided up into private wards for which there has been a great demand recently. The addition will be greatly to the advantage of the medical students of Laval University.

Closing Exercises at Queen's University.—Queen's medical convocation ceremonies took place on the afternoon of April 8. Dr. Herald, the secretary, reported that the attendance at the medical department during the session just closed was 177, the largest in the history of that faculty of the University. G. F. Dalton, Kingston, was medallist in surgery; F. E. Mellow, medallist in medicine; house surgeons for the Kingston General Hospital for next year are: G. F. Dalton, C. Destremy and F. Etherington.

Insanity Increasing in Montreal.—Mayor Cochrane of Montreal states that he is shocked at the number of persons he daily has to commit to the insane asylum. He commits on the average two patients per day. Persons committed by the corporation have to be supported in the institutions by the corporation; and owing to the large numbers the mayor is of the opinion that these are sent in to the city from outside points to friends and are thus foisted on the charity of the city. He will cause the city council to make an enquiry into the matter.

Right of City to Send Smallpox Patients to Hospital.—Owing to the fact that some persons affected with smallpox in Montreal refused to go to the city hospital, one individual going so far as to say that he would split open the head of any doctor or officer who entered his house for the purpose of removing him, the Hygienic Committee has asked that the city attorneys make a report to council on the right of the city to compel patients suffering from infectious diseases to go to the civic hospital. The report will no doubt be awaited with interest.

Ontario Board of Health.—The regular quarterly meeting of the Ontario Board of Health was held in Toronto during the past week. Dr. Bryce, the secretary, presented an interesting report on the smallpox outbreak, which is summarized in another column. Dr. Bryce also presented an extensive report on the mortality returns, claiming that there was altogether too much "heart failure" set down as the cause of death. On this report an interesting discussion arose as regards the duties and responsibilities of coroners, it being held that the

law should be amended so that these officers should not be required to make affidavits that there were no evidences of foul play before they had actually made a thorough investigation. Ontario, with 2500 doctors, has over 500 coroners.

**Canada Has Immigration Problems.**—Owing to the increased surveillance at the border by American officials, about 100 foreigners desiring admission to the United States are refused each week. Mr. Robert Watchorn, special immigration inspector of the United States in Canada, has started the dominion by the statement that 98 per cent. of these immigrants are suffering from serious and most infectious diseases. The two chief diseases mentioned are trachoma and favus. Mr. Watchorn calls the attention of Canada to the fact that these persons largely remain in Canada. The statistics show what a nice measure the United States took when the tide of emigration, checked at the seaports, turned to the unprotected Canadian border for an unhindered entrance. Parliament will doubtless make a speedy investigation. It is interesting in this connection to note Canada's active immigration propaganda. Mr. R. W. Hilliard, the Canadian traveling immigration agent, reports that he learns that about 75,000 people from the Northern and Western States are contemplating removing to the Canadian Northwest. The continual loss that the United States suffers in this way is largely of healthy, desirable farmers, and is of moment to the states affected, as well as to those physicians whose practices are lessened by it. However, one valuable feature is that it binds Canada and the United States by one of the firmest of ties.

#### FOREIGN.

**The Barcelona Academy of Medical Sciences** offers a prize of 2500 pesetas for the best work in Italian, French, Portuguese or Spanish on "Comparative Histology of the *Forea Centralis*," received before December 31.

**Grecian Medical Congress.**—The second Pan-Hellenic Medical Congress will convene at Athens May 17 to 21, 1903. Paludism in its various aspects will be one of the subjects chiefly discussed, especially in its relations to pregnancy and malignant disease.

**International Congress of Electrotherapy and Radiography.**—The first congress was held at Paris in 1900. The second will convene at Berne, Sept. 1 to 6, 1902. Communications should be sent to the secretary, Dr. Schnyder, Bundesgasse 38, Berne, before July 15. The fee is 25 francs.

**Literary Property in the Medical Press.**—The report to be presented by the committee to start the discussion of this subject at the International Conference of Delegates from the Medical Press at Monaco, April 7, was based on the following principles: "1. Original articles, lectures and, in general, all solid articles have unquestionably the rights of private property. They should not be reproduced nor translated without indication of the original source and even this should not be done without the authorization of the journal. Abstracts can be made of these articles without authorization, provided that the original source is duly credited. However, if the abstract only refers to a limited portion or point of the subject treated, the name of the author alone may be sufficient. 2. Other articles, transactions of societies and congresses, abstracts or reviews of articles already published, scientific letters, professional interests, etc., may be reproduced or translated without authorization, under the express condition that the periodical from which they are taken is indicated, and also the original source of the abstracts. 3. The reproduction of news, medical items, 'varia,' and all other items of this nature, is absolutely free." The committee added that they hoped the discussion would be based on these principles. They presented these rather strict regulations in order that the matter might be discussed along the lines and principles accepted by the periodical press of all the countries in the Postal Union.

**The Fourteenth International Medical Congress** will be opened in Madrid, Spain, April 23, 1903, and close April 30. Dr. Abraham Jacobi, having been requested by the officers of the Congress to form the American committee, has arranged that the plan devised by Dr. William Osler, which worked so well in preparation for the thirteenth congress, shall be followed also for the fourteenth. Invitations to accept places on the committee have therefore been sent to the presidents of the American Medical Association, American Congress of Physicians and Surgeons, and of the fourteen constituent societies and associations of the American Congress, the Surgeon-General of the Army, Navy and Marine-Hospital Service, the President of the Canadian Medical Association and the President of the National Dental Association. Acceptances have been received from nearly all of those invited. Dr. Howard A.

Kelly of Johns Hopkins University will deliver the address at one of the general meetings of the Congress. He has chosen for his subject "The Passing of a Specialty." Dr. Ramon Guiteras has been appointed delegate to the Congress by the New York Academy of Medicine. The committee to date consists of W. W. Keen, M.D., Philadelphia, President of the American Congress of Physicians and Surgeons; John C. Wyeth, M.D., New York, President of the American Medical Association; R. H. Chittenden, M.D., New Haven, President of the American Physiological Society; Walter S. Christopher, M.D., Chicago, President of the American Pediatric Society; Joseph Collins, M.D., New York, President of the American Neurological Association; John W. Farlow, M.D., Boston, President of the American Laryngological Association; Samuel A. Fisk, M.D., of Denver, President of the American Climatological Association; S. C. Gordon, M.D., Portland, Me., President of the American Gynecological Society; Geo. T. Jackson, M.D., New York, President of the American Dermatological Association; Horace G. Miller, M.D., Providence, President of the American Otological Society; Presley M. Rixey, M.D., Washington, Surgeon-General of the Navy; F. J. Shepherd, M.D., Montreal, President of the Canadian Medical Association; George M. Sternberg, M.D., Washington, Surgeon-General of the Army; O. F. Wadsworth, M.D., Boston, President of the American Ophthalmological Society; DeForest Willard, M.D., Philadelphia, President of the American Surgical Association; H. August Wilson, M.D., Philadelphia, President of the American Orthopedic Association; James C. Wilson, M.D., Philadelphia, President of the Association of American Physicians; Walter Wyman, M.D., Washington, Surgeon-General of the Marine-Hospital Service; Abraham Jacobi, M.D., New York, chairman. The secretary of the American committee is John H. Huddleston, M.D., 126 West 85th St., New York City.

#### LONDON LETTER.

##### The Smallpox Epidemic.

The number of cases of smallpox in the metropolitan hospitals at the end of last week was 1567 against 1309, 1508 and 1542 in the three preceding weeks; 449 new cases were admitted during the week against 369, 554 and 450 in the three preceding weeks. The total number of cases since the commencement of the epidemic is 5267. Of these 3246 have been discharged cured and 750 have died. From extra-metropolitan districts, 574 cases have been admitted to the metropolitan hospitals. The incidence of the disease in London has now been 1 in 870 persons. The daily admissions show that the disease is still progressing. The average daily admissions in January were rather less than 42, in February just over 56, and in March, up to the 20th, 70 a day.

The number of patients in hospitals this week is 1526, against 1508, 1542 and 1567 in the three preceding weeks; 389 new cases were admitted during the week against 554, 450 and 449 in the three preceding weeks.

##### Vaccination. Government Control of Lymph.

At the annual meeting of the Hospital Saturday Fund (an institution which collects money for the metropolitan hospitals on a certain Saturday every year, and last year collected \$100,000) Dr. T. D. Acland made an important statement based on his seven years' experience as medical officer to the Royal Commission on Vaccination. More than 6,500,000 vaccinations were brought under the notice of the commission and in these serious injury occurred in one case in 14,159 primary vaccinations. But more than half of these were due to preventable causes, namely, the various kinds of inflammation. Having given facts and statistics to show the protective power of vaccination against smallpox he advocated arrangements by the government for an adequate supply of lymph of the best quality. A motion was carried that "The government should establish a laboratory fitted in the most perfect manner, adequate to supply all practitioners throughout the United Kingdom with vaccine lymph; and that they should inspect all establishments for the preparation of lymph in this country and regulate the sale of all that is imported."

##### Paralysis of the Cervical Sympathetic from a Bullet Wound.

At the Clinical Society Dr. J. Purves Stewart exhibited the following case: The patient was a soldier, aged 26, who had been wounded 14 months previously by a Mauser bullet, which entered the left side of the neck  $1\frac{1}{2}$  inches below the mastoid process and came out in the seventh right intercostal space in the posterior axillary line. The bullet thus passed in front

of the vertebral column. He had temporary total paralysis of the right arm, which gradually cleared up. There was some hemoptysis and slight dysphagia for a few days. Ever since the injury the sight in the right eye had been less acute than in the left, and he had noticed that he did not sweat on the right side of the face, scalp, neck or upper limb. As regards the present condition, there were slight weaknesses of the small muscles of the right hand, and an area of slight analgesia along the inner border of the upper arm, forearm and hand, including one and a half fingers, with a small patch in the axilla. The right pupil was smaller than the left, and did not dilate when shaded. Both pupils reacted briskly to light and on convergence. The cilio-spinal reflex was absent on the right side. The right palpebral fissure was narrower than the left, and the right eye was slightly sunken. He did not sweat on the right side of the face, scalp, neck, upper part of the thorax, or upper extremity. This area of anidrosis was bounded by the middle line and extended down as far as the third rib in front and posteriorly as far as the middle of the scapula. The lesion was apparently one of the first dorsal nerve-root on the right side, involving the cervical sympathetic.

#### The Increase of Cancer.

It is an observation in all civilized countries that cancer has greatly increased in the last generation. The subject has been repeatedly discussed in England. An attempt was made, but not successfully, to show that the increase is only apparent, and that the increased number of deaths from cancer registered are the result of more accurate diagnosis in the present day. Two very important papers have just been read on the subject at the Chelsea Clinical Society. Dr. J. Tatham, superintendent of statistics at the General Register office, said that during the last four years the annual number of deaths from cancer (using the term for all forms of malignant diseases) in England and Wales has averaged more than 25,000. According to the latest returns the male death-rate from cancer in England and Wales is 672 per 1,000,000 living, while female death rate is not less than 975 per 1,000,000. This excess was due to the tendency of malignant diseases to attack the generative organs of the female more than those of the male. When the deaths from cancerous affections of ovaries, uterus and breast were subtracted from the total cancer deaths of females, the remainder gives a death rate among females which is considerably below that among males. Thus, in the four years, 1897-1900, the male deaths from cancer, less the deaths from disease of the organs referred to, corresponded to a death rate of 645 per 1,000,000, while the female rate with the same limitations did not exceed 568 per 1,000,000. The official figures show the appalling fact that the cancer death rate is more than double what it was 30 years ago. In the decade, 1861-1870, the average annual death rate from cancer per million living was 242 in males and 519 in females; in the decade, 1891 to 1900, the rates were respectively 597 and 903. Thus, although at present women suffer much more severely than men from malignant disease, nevertheless the disease during the last 30 years had increased among men much more rapidly than among women. Sir William Banks, the eminent Liverpool surgeon, said that he was absolutely certain that cancer now appears at a much earlier period of life than formerly. In discussing the cause of cancer he referred to the fact of its prevalence near rivers that periodically overflowed their banks and low damp situations, especially those with a clay soil. The parts where there is the least cancer are the high situations, especially those with a chalk formation. He thought that the great increase of the disease was due to the great amount of food, especially meat, consumed now by the people. There was no longer a class such as existed 50 years ago who ate meat only once a week. Wretched, half-starved patients were not the most prone to cancer, but well-nourished persons with plenty of fat and often with the color of health in their cheeks. However, this view, which has been advocated before, has been confuted. Dr. Reiche of Hamburg has shown that the increase of cancer in Hamburg in the last 30 years occurred equally in the poor and ill-fed part of the town and in the rich and prosperous. A much more plausible cause for the increase of cancer is that given by Mr. Jonathan Hutchinson, i. e., increase of longevity.

#### The Medical Graduates' College and Polyclinic.

At the third annual general meeting, the annual report records a gratifying and steady increase in all departments, showing the polyclinic filled a real and long-felt want. The attendances at the practical classes have been considerably augmented and on one or two occasions the entries have been so

numerous that a duplication of the courses was necessitated. The register shows the total number of life members, members, subscribers and temporary subscribers to be for the year 1901 825, against 615 for 1899 and 674 for 1900. The special committees formed for dealing with leprosy, yaws, climatology and tuberculosis have held several meetings, and two new special committees for the study of cancer and vaccination are in course of formation. The short courses on special subjects, which were inaugurated in October, 1900, have proved so attractive that their number during the past year has been doubled. The work of the consultation is steadily increasing, and it was pointed out that a great many more members availed themselves of its opportunities than formerly. In the past year 150 clinical investigations have been carried out in the laboratory. The museum has been enriched during the year by many valuable additions. The net profit that accrued to the college funds as a result of the dinner held at the Hotel Cecil on May 22 last was £1163.

## Correspondence.

### Reprints, Whence They Come and Whither They Should Go.

DENVER, COLO., March 28, 1902.

*To the Editor:*—There is an inborn craving in the hearts of medical men for reprints of their articles. The explanation of this universal phenomenon is based on a psychological fact, namely, that every writer wishes to give the stamp of individuality to his work. An article in a modern periodical is like a pin in a stack of hay. That an article nowadays may make a lasting impression upon the reader, it must be an extraordinary production, indeed. The individuality and force of the majority of writings is obliterated in the "crowd." Hence, the writer unconsciously makes an attempt to rescue his production from oblivion by giving it at least the form of individuality. A reprint is an entity, a whole, not a part of a conglomerate.

There is, besides, a utilitarian reason for the existence of the reprint. It is a time-saving contrivance, since it is easier to handle and, therefore, more serviceable for purposes of reference. Especially is it true in the case of long articles running through several numbers of a periodical. By using a reprint one avoids the annoyance of hunting for continuations through a maze of irrelevant literature.

The reprint, furthermore, possesses an altruistic element, namely, the socialization of ideas. By sending out reprints, one is enabled to call the attention of his colleagues to some new idea, to some particular point. By individualizing and bringing one's work into bolder relief the writer may have the satisfaction of seeing his ideas either accepted or justly refuted. The reprint then becomes a source of mutual benefit.

In the majority of cases, however, the sending out of reprints instead of being a mutual benefit, is nothing but a mutual fraud. They are sent out, not with a view of being read and preserved by the recipient, but simply as a hollow courtesy, which *faire des compliments* is reciprocated in the same spirit. Of one thousand reprints sent out, one will not be far from the mark in saying that not fifty will be read, and not a dozen will be preserved for future reference.

Any one who doubts the above assertion should make the following experiment: Ask of all of those to whom you sent out your reprints, say, six months ago, to return you a copy. You will soon be convinced that your reprints, the writing, printing and mailing of which cost you labor and money, have all gone the way of the daily newspaper.

The fun of the matter is that you have no right to grumble or to be indignant at your fellow-man, for you, too, have been the happy recipient during the last six months of many reprints, to whose authors (after having deposited their missives into the waste basket) you have probably addressed a courteous note, thanking them for their "valuable contributions." How many have *you* read? How many have *you* preserved?

This exchange of compliments is downright mockery and self-deception. The present system of sending out reprints promiscuously is a failure. A radical change is imperative.

#### SEND YOUR REPRINTS TO THOSE WHO WILL READ THEM.

If any one is more liable to read your reprints than another it is he who himself has contributed to the subject treated in your article. Look over several volumes of the periodical and find out the names of authors who have written already on the subject, and send them your reprint. They will undoubtedly read it, possibly preserve it.

If you wish to awaken an interest in your subject in such whom you do not know, mark with a blue pencil the most salient points in your reprint, and write on the title page "Pages so and so marked." This will insure a glance at least, perhaps a perusal.

#### SEND YOUR REPRINTS TO MEDICAL LIBRARIES.

A medical library is the only place where your reprint will certainly go to the shelf instead of to the basket. There your reprint will be smoothed out, catalogued under your name and under the name of the subject you treat of, be bound and eventually read with profit. If you have contributed anything of value, be sure sooner or later your work will be read by a colleague unknown to you, perhaps thousands of miles away from you. Many ideas ripen and become digestible under the dust of book shelves. In years to come, when you have already forgotten your own work, you may have the satisfaction of seeing yourself quoted or referred to. Your friends may have sent your reprints to the paper mill, or burned them in a fit of "cleaning up rubbish"; nay, your own copies may have disappeared from the face of the earth, yet your reprints still live. By sending them to libraries you have secured for them a home where they will be tenderly cared for and preserved for all time.

Let the medical libraries be the first claimants upon your reprints. We live in the work we leave behind us. By placing our reprints in medical libraries we are reaching out for immortality.

C. D. SPIVAK, M.D.,

Sec. Colorado Medical Library Association, Editor of  
*Medical Libraries.*

## State Boards of Registration.

**Pennsylvania Examiners.**—At the examination in December by the Pennsylvania State Medical Boards, there were 105 applicants for certificates before the Regular Board, 21 failing to pass; 9 applicants before the Homeopathic Board, 4 failing to pass.

**New York State Examination.**—The New York State Board of Medical Examiners held an examination at Albany, in January. The number of subjects examined in were 7; percentage required, 75. The total number of applicants was 113, of whom 79 passed.

**Montana Osteopaths.**—The state board of osteopathic examiners elected the following officers on March 5: Dr. Asa Willard, Dillon, president; Dr. C. W. Mahaffy, Helena, secretary, and Dr. O. B. Prickett, Billings, treasurer. Of 26 applicants examined during the year, all have passed.

**Missouri Examination.**—At Jefferson City, January 7, the Missouri State Board of Health examined 31 candidates, of whom 14 passed and 17 failed. The written examination covered 11 subjects with 110 questions, the percentage necessary to pass being 75. The successful regular candidates were graduates of the following schools: University of Basel, Germany; University of Berlin, Germany; Imperial University, Austria; Johns Hopkins, Baltimore, Md.; Marion-Sims, St. Louis; Marion-Sims-Baumont, St. Louis (three); Denver Medical College, Colorado; Miami Medical College, Cincinnati; American Medical College, St. Louis (two); University of Pennsylvania. There was one member of the Homeopathic school licensed, a graduate of Hahnemann Medical College, Chicago. The board objects to furnishing the percentages attained by applicants and the data concerning those who failed.

**Examinations in Many States.**—The spring meetings of examining boards have been in session in many states during the past few weeks.—The Montana Board, at Helena, April 3, granted licenses to 13 out of 20 applicants. Dr. F. W. McCrimmon, Butte, was elected president; Dr. William C. Riddell, secretary, and Dr. George H. Barbour, treasurer. The next session is in October.—Twenty-one candidates were examined by the Minnesota Board at St. Paul, March 31, April 1 and 2.—Wisconsin candidates numbered about 20 at Milwaukee, April 7 to 9.—About 100 applicants met the Missouri Board of Health at Kansas City, April 2.—Iowa aspirants were examined, April 3-5, at Iowa City.—The Indiana State Board met at the capitol, April 10.—Tennessee examiners divided their forces, according to law, and examined candidates in Nashville, Knoxville and Memphis, April 3. Under the law as it now stands graduates of Tennessee colleges are entitled to license without examination, but next year's and succeeding graduates must be examined.—In Pennsylvania the next examination will be June 25 to 28, at Pittsburg and Harrisburg. The board met, April 2, at Pittsburg and elected these officers: President, Henry Beates, Jr., Philadelphia; secretary, H. S. McConnell, New Brighton.—The Illinois Board examined 137 candidates at Chicago, April 9-11, of whom 98 desired license as physicians, 28 as osteopaths, and 11 as midwives.

**Results in Maine Examination.**—At Portland, March 18, the Maine Board of Registration in Medicine examined 6 applicants and passed 4, there being 7 subjects with 70 questions, part oral and part written. The percentage necessary to pass was 75.

## Book Notices.

ALCOHOLISM, A Study in Heredity. By G. Archdall Reid, M.B., C.M., F.R.S.E., Author of "The Present Evolution of Man." Cloth. Pp. 293. Price, \$2.50. New York: Wm. Wood & Co. 1901.

Dr. Archdall Reid is the champion, we might say, of certain extreme views. It is perhaps not unfair to say that he believes that drunkenness exalted the nation by weeding out its defectives. The present work is an argument to this effect drawn out at length. Many of his alleged facts are open to dispute and his deductions are still more disputable. The inference that the Northern races have not become immune to alcoholism, while the Southern Europeans have become resistant from long usage and, therefore, temperate, seems unsupported. In fact, the Northern Europeans, the Scandinavians, British, etc., have in all times been drinkers and on the other hand temperance as such is not universal among the Southern Slavs nor even in the so-called Latin race. His statements as regards the effects of prohibition are the commonly repeated ones of the anti-temperance advocates in this country and one does not need to be fanatical to have to admit that they are not absolutely based on facts. Prohibition does prohibit to a marked extent in rural districts, but in the large towns it has been more or less a failure. It

certainly makes a difference, however, in the community and in the State to have prohibition laws on the statute books. His absolute acceptance of the "for revenue only" findings of the British opium commission in India is also striking. For positiveness of statement and general contempt for all who disagree with him we think Dr. Reid has hardly a rival among medical writers, and he utterly ignores a very large and respectable class of biologists and naturalists whose theories are opposed to his own as well as many illustrious medical authorities. The fact of the evil heredity of parental drunkenness is probably as well demonstrated as any medical fact existing, yet he will not admit it. He seems to entirely ignore the statistics in regard to this point of those who have studied the defective classes, especially in France. We would assume from the internal evidence that Archdall Reid is probably the chief author of the report of the Committee on the heredity of inebriety which is published in the appendix. The acknowledgment that the committee adopted the researches of Dr. Reid on national peculiarities and did not itself make any investigation of the subject, we think bears out our opinion. The book is a readable one and will have its place in the literature of inebriety and anti-temperance reform.

PRINCIPLES AND PRACTICE OF OPERATIVE DENTISTRY. By John Sayre Marshall, M.D. (Syr. Univ.), Dental Surgeon, U. S. A. Cloth. Pp. 635. Price, \$5.00. Philadelphia and London: J. B. Lippincott Co. 1901.

The author has shown decided skill in classification and arrangement of the topics discussed in the various chapters. The departments are arranged in a progressive, comprehensive style. Methods of constructing artificial crowns and bridge-work, orthodontia and other similar subjects that do not properly come under the head of operative dentistry have been eliminated. Those considered as pertaining to operative dentistry, such as dental embryology histology, bacteriology, anatomy and pathology, are handled in a masterly manner.

No one can write a work on science at the present time which would be entirely original. This is particularly true of operative dentistry. The present methods of operating are the evolution of sixty years of practice. Operative dentistry, however, does not admit of a wide range of development. The compilation and arrangement are well done. Unlike many dental authors, Dr. Marshall has given credit to those from whom he has obtained material. He has discussed many subjects that are very important to the dentist outside of filling teeth. General and special pathology are lacking in dental schools; hence, this new departure will have a beneficial influence.

Fine photomicrographs by Dr. Vida A. Latham illustrate the chapters on origin, development and histology of the dental tissue; bacteriology of the mouth; dental caries; diseases and injuries of the dental pulp, and render the work equally interesting to student and practitioner. New illustrations by Drs. Andrews, Miller, Williams, Cryer, Noyes, Vincentine, James S. Shearer, together with originality in text, place this work in advance of other text-books on the subject. It is admirably adapted to both student and the busy practitioner, because nearly everything pertaining to the various subjects is found up to date.

MORPHINISM AND NARCOMANIA from Opium, Cocain, Ether, Chloral, Chloroform, and Other Narcotic Drugs; Also the Etiology, Treatment, and Medical Relations. By T. D. Crothers, M. L., Superintendent of Walnut Lodge Hospital, Conn. Handsome 12mo of 351 pages. Cloth. Price, \$2.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This work is, as the author states, a practical summary of clinical experience of over one-quarter of a century in active treatment and care of narcomaniacs and as such it has a very decided value. The scarcity of literature also on the subject is mentioned by the author in the preface, as comparatively few text-books or treatises give the subject full consideration. It is therefore a valuable addition to the medical literature and the reader will find in it a large amount of well-described facts and suggestions. The author's views on inebriety of all kinds as a disease are well known. It is not necessary, of course, to agree with him in every point, but most of us, if not all, will be better for the information he can give. We would have been glad to have had him state, for example, the average daily amount of morphin consumed by

the ordinary morphin fiend, but we do not see it given in the work, nor the average amount given by different methods. Such a fact would be of value in estimating the number of such cases in a district where the sales are reported, as some alarming statistics have been sent out comparatively recently on this subject. We do not believe that morphin-taking is so widespread a habit as some claim, though it is far too common in every civilized country. The work is neatly printed and in the concluding chapters are given some well-known facts in regard to other drug addictions, such as chloroform, coffee and tea inebriates. The latest details in regard to the effects of methyl alcohol on the eye are not given, which seems to have been an oversight, but the data are so comparatively recent that the omission may be excusable.

**THE ROENTGEN RAYS IN MEDICAL WORK.** By David Walsh, M.D. Edin., Physician Western Skin Hospital, London, W. Part I—Apparatus and Methods. Rewritten by Lewis Jones, M.D., Cantab., F.R.C.P., Medical Officer in Charge of Electrical Department of St. Bartholomew's Hospital. Part II—Medical and Surgical. Third Edition. Cloth. Pp. 316. Price, \$2.50. New York: Wm. Wood & Co. 1902.

Since the discovery of the Roentgen rays a new specialty accessory to medicine has arisen. While not every physician can master all the facts and details required for a thorough knowledge of the subject, the practical features of skiagraphy so far as they relate to medicine and surgery are particularly well summarized in the present volume. The fact that it has gone through two editions is sufficient evidence of its having met a need. Recent as this publication is, it is necessarily a little behind the time in such a progressive specialty as this department of electric science. A number of recent publications have appeared which contain facts that might well have been included, but on the whole we know of no better book as a compendium of the present knowledge.

**RECHERCHES CLINIQUES ET THERAPEUTIQUES SUR L'EPILEPSIE, L'HYSTERIE, ET L'IDIOTIE.** Compte-rendu du Service des Enfants Idiots, Epileptiques et Arriérés de Bicêtre Pendant L'Année 1900. Par Bourneville avec en collaboration de MM. Crouzon, Dionis de Séjour, Izard, Laurens, Paul-Boncour, Philippe et Oberthur. Volume XXI. Avec 19 figures dans le texte et XI planches. Paris: Progrès Médical. 1901.

- This volume, which forms the report on the idiot, epileptic and feeble-minded departments of the Bicêtre under Bourneville, is, like its predecessors, a valuable contribution. The papers it contains are of unequal length, but all of them of more or less special interest. Among them may be mentioned the account of a family cerebrospinal disease by Bourneville and Crouzon, consanguinity in the etiology of epilepsy and alcoholism in the production of these diseases by Bourneville, statistics of the persistence of thymus, the data on the skull in idiocy, microcephalism, etc. This series of works will be of permanent value as containing valuable data in regard to defective humanity.

**NURSING, GENERAL, MEDICAL AND SURGICAL.** With Appendix on Sick-room Cookery. By Wilfred J. Hadley, M.D., F.R.C.P., F.R.C.S., Physician and Pathologist to the London Hospital. Cloth. Pp. 326. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1902.

Among the various books on nursing which have recently appeared this is the latest, and it appears to be fairly well adapted to its purposes. The arrangement perhaps is a little to be criticised. The question occurs to some of us as physicians whether the little knowledge of diseases given in the matter of the larger portion of this book is always a necessary part of the nurse's accomplishments. It is far from being complete, though in the main the information given seems to be correct. The description of the various special duties of the nurse comprises only a small portion of the work and some little nursing wrinkles that are taught in nursing schools are not mentioned. The appendix on sick-room cookery, though brief, is a useful addition.

**VALID OBJECTIONS TO SO-CALLED CHRISTIAN SCIENCE.** By Rev. Andrew F. Underhill, Rector of St. John's Church, Yonkers, N. Y. Paper. Pp. 49. Price, 25 cents. New York: Edwin S. Gorham. 1902.

The substance of this book was contained in two discourses delivered in Yonkers last January. It is dedicated to "the physicians of Yonkers in recognition of their progressive scientific spirit and unselfish devotion to the cause of humanity." The author shows that Eddyism is neither Christian nor scientific; neither ethical nor moral; that it is purely specu-

lative; and that it is in opposition to all physical and hygienic laws, and to all common sense and reason. It will make an excellent little book for physicians to place in the hands of those of their patients who are open to conviction.

**KIRKE'S HANDBOOK OF PHYSIOLOGY.** By W. D. Halliburton, M.D., F.R.S., Professor of Physiology, King's College, London. Seventeenth Edition, with 681 Illustrations. 12mo, 888 pages. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

It has been only two or three years since we noticed the last prior edition of this well-known handbook, which should really be called Halliburton's Physiology. This seventeenth edition has been thoroughly revised, and although it only exceeds the former one by fifteen pages, which are due largely to increased illustrations, sufficient unnecessary typography has been excised to leave a considerable amount of space for new matter, bringing the work as fairly up to date as can be reasonably expected. Any work on physiology rapidly changes in details; the science is a progressive one; hence, the necessity of frequent new editions. The book will undoubtedly retain the favor which it has so long held in professional public opinion.

**THE POCKET GRAY, OR ANATOMIST'S VADE-MECUM.** By the Late Edward Cotterell, F.R.C.S., Fifth Edition, Revised and Edited by C. H. Fagge, M.B., M.S., Lond., F.R.C.S., Senior Demonstrator of Anatomy, Guy's Hospital. Twentieth Thousand. Cloth. Pp. 269. Price, \$1.25. New York: Wm. Wood & Co.

The fact that this is the fifth edition of this little work shows its popularity. It is a very convenient reminder of anatomic facts prepared in pocket size. There is no one whose memory is so perfect on everything in our complicated mechanism that he will not find such a reference book occasionally of use. The work is not absolutely complete, as the skeleton aside from the articulations is not included in its matter, but this, probably, is purposely omitted for the saving of space.

**ROUGH NOTES ON REMEDIES.** By Wm. Murray, M.D., F.R.C.P., Lond., Newcastle-on-Tyne. Fourth Edition. Cloth. Pp. 176. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1901.

This little volume, which has arrived at the fourth edition, consists only of a few scattered papers of the practical type that have attracted the attention of the average physician. Some of them are generally interesting, others are purely local, especially the later ones which have been added to this edition, bearing on the local conditions as to health resorts, etc., in Great Britain. One paper which is simply an advertisement of a special kind of alcoholic drink is hardly commendable in a general way.

**AN INTRODUCTION TO THE CHEMICAL ANALYSIS for Students of Medicine, Pharmacy and Dentistry.** By Elbert W. Rockwood, M.A., M.D., Professor of Chemistry and Toxicology in the Medical, Dental and Pharmaceutical Departments of the University of Iowa. Illustrated. Cloth. Pp. 255. Price, \$1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This volume is intended as a handbook for students in their analytic work in the course of medical college instruction. It is not intended, the author says, to make analytic chemists, but to give something more than a mere smattering in this particular line of work. We should think from our examination of the work that it would be a convenient and useful adjunct to the student's medical course.

**ON THE CURE OF THE MORPHIA HABIT WITHOUT SUFFERING.** With a Note on the Physiologic Method of Relieving the Craving for Drink. By Oscar Jennings, M.D. (Paris), M.R.C.S. (Eng.), Fellow of the Royal Medico-Chirurgical Society. Second Edition, Revised and Enlarged. Cloth. Pp. 211. Price, \$1.50. New York: Wm. Wood & Co. 1901.

For ten years this has deservedly been a sort of standard work in Great Britain. The methods described are rational and we do not know of any small monograph on the subject that answers the purpose any better. The author has rewritten a number of chapters and changed the order of others, introducing new illustrative cases. The book is one that can be recommended.

**MANUAL OF PHYSICAL DIAGNOSIS.** For the Use of Students and Physicians. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the University Hospital. Fourth Edition, Revised and Enlarged, with Colored and Other Illustrations. 12mo. Cloth, \$1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This is the fourth edition of a well-known manual which has been carefully read, revised and brought up to date by the author. That it has already received such success, shows its estimation by the profession.

## Married.

JOSEPH C. BUSSEY, M.D., to Miss Julia Isaacs, both of Louisa, Ky., March 17.

ELIZABETH JOHNSON, M.D., to Rev. Evert Van Slyke, both of New York City, April 3.

LOUIS T. KENNEDY, M.D., to Miss Harriett Bland, both of Pottsville, Pa., April 1.

M. H. THOMAS, M.D., to Miss Cosette Watkins, both of Huntington, Ind., March 30.

JOHN C. HOYE, M.D., to Mrs. Elizabeth McGraw, both of Newcastle, Pa., April 2.

HUGH P. FLEMING, M.D., to Miss Ethel Gormully, both of Ottawa, Ontario, April 16.

GEORGE D. SITZEP, M.D., to Mrs. L. Grace Thomas, both of Charles City, Iowa, April 1.

WALTER REEVE RAMSEY, M.D., to Miss Ruth Albia Lusk, both of St. Paul, Minn., April 19.

JACOB M. MCWILLIAMS, M.D., to Miss Ova Goodner, both of Fayetteville, Tenn., March 26.

M. M. HALLUM, M.D., Carrollton, Ga., to Miss Beulah Murphy, of Newnan, Ga., March 26.

MALCOLM S. COUNCIL, M.D., Bryn Mawr, Pa., to Miss Helen Duer, of Philadelphia, March 31.

WILLIAM H. CUSHING, M.D., to Miss Gertrude E. Kranich, both of Southampton, Conn., April 31.

HENRY E. ARMSTRONG, M.D., Billings, Mont., to Mrs. Mattie Capple, at Los Angeles, Cal., March 4.

WILLIAM HOUSTON TANKSLEY, M.D., to Miss Laura Hayes Webb, both of Nashville, Tenn., April 2.

ARTHUR M. JOHNSON, M.D., Rochester, N. Y., to Miss Lucy E. Finch, of Binghamton, N. Y., March 31.

RAY BURNEY TUBBS, M.D., of Tacoma, Wash., to Miss Ethel Percy Opdyke, of Plainfield, N. J., March 15.

HARRY WALSH, M.D., Chickasaw, I. T., to Miss Bessie De Verter, of Lodi, Ind., at Chickasaw, March 27.

THOMAS JEFFERSON DAVIS, M.D., Jordan, S. C., to Miss Minerva Goode Holden, of Petersburg, Va., April 8.

WILLIAM J. RITCHIE, M.D., Warren, Ohio, to Miss Edith Maud Clement, of Brantford, Ontario, April 16.

FRANCIS WALTER ERNEST WILSON, M.D., to Miss Mary Victoria Beatrice Ferguson, both of Niagara Falls South, Ontario, March 31.

HENRY GIDEON WELLS, M.D., a member of the faculty of the University of Chicago, to Miss Bertha Robbins, of Newington, Conn., April 2.

CLARENCE W. WILLE, M.D., assistant surgeon, U. S. Marine-Hospital Service, Old Point Comfort, Va., to Miss Helen Davis Hague, of Elkton, Md., March 26.

DR. AND MRS. JAMES THOMAS JELKS, Hot Springs, Ark., announce the marriage of their daughter, Julia Roberta, to Mr. William C. Morris, of Pony, Mont., April 8.

## Deaths and Obituaries.

**John Kennington Leaning, M.D.** Castleton (Vt.) Medical College, 1848, a prominent physician of Cooperstown, N. Y., died at his home in that place, April 4, after an illness of five days, from pneumonia, aged 78. Dr. Leaning had practiced medicine in Otsego County for 54 years. He was a member of the County Medical Society, the New York State Medical Association and the American Medical Association. He was also president of the medical board of Thanksgiving Hospital, Cooperstown. Otsego County Medical Society, at a special meeting held in Cooperstown, April 7, passed resolutions of sorrow and sympathy.

**William L. Williams, M.D.** Medical College of Virginia, Richmond, 1841, one of the oldest, most successful and highly-esteemed physicians of Virginia, who had practiced in Nelson County for more than 50 years, and had served his county in the state legislature, died at his home in Avon, after a painful illness, April 8, aged 83.

**John Ahl, M.D.** College of Physicians and Surgeons, Baltimore, Md., 1875, one of the oldest physicians of York, Pa., who had at times filled the positions of coroner, jail and almshouse

physician and health officer, died from senile gangrene at his home in York, April 4, after an illness of three months, aged 79.

**Thompson D. Fisher, M.D.** Rush Medical College, Chicago, 1857, a retired physician, of Leroy, Ill., some-time president of the McLean County Medical Society and a member of the Illinois State Medical Society, died at his home in Leroy, April 6, after an illness of two weeks, aged 75.

**John L. Eddy, M.D.** Castleton (Vt.) Medical College, 1854, one of the most prominent physicians of Western New York, a veteran of the Civil war, and at one time president of the State Association of Railway Surgeons, died suddenly at his home in Olean, N. Y., April 5, aged 73.

**John Eccles, M.D.** University of Pennsylvania, Philadelphia, 1896, a former practitioner of Philadelphia, who had been for two years a medical missionary in Central America, died from septicemia at the United Fruit Company's Hospital, Bocas del Toro, Colombia, January 18.

**J. W. H. Vest, M.D.** Starling Medical College, Columbus, Ohio, 1847, a practitioner of Montezuma and Des Moines, Iowa, since 1856, a surgeon and later medical director of an army corps in the Civil war, died at the home of his son in Montezuma, April 5, aged 79.

**Ulick W. C. Burke, M.D.** Bellevue Hospital Medical College, New York, 1880, a specialist in diseases of the gastrointestinal tract, died at his home in Brooklyn, April 3, from heart disease, after an illness of two weeks.

**William E. Huger, Jr., M.D.** University of Virginia, Charlottesville, 1897, assistant on surgical staff of the Johns Hopkins Hospital, Baltimore, died in that institution, March 29, from typhoid fever, after a short illness.

**Henry C. Linn, M.D.** Washington University, St. Louis, 1864, who had practiced medicine since 1833 and was the oldest physician and resident of Butler, Pa., died suddenly at his home in that place, April 3, aged 90.

**William J. Poe, M.D.** Memphis (Tenn.) Hospital Medical College, 1893, formerly of De Leon, Texas, but for the last three years a practitioner of Carbon, Texas, died at his home in that place, April 6, from pneumonia.

**Francis M. Gunnell, M.D.** National Medical College, Washington, D. C., 1846, formerly a surgeon in the United States Navy, who was retired for age in 1889, died at his home in Washington, April 5, aged 74.

**John H. Blau, M.D.** University of Gratz, Austria, 1852, a pioneer physician of Covington, Ky., who had been in practice for 50 years in that place, died at his residence, April 3, after a long illness, aged 69.

**James T. Atchison, M.D.** University of Louisville (Ky.), 1857, one of the most widely-known practitioners of Jefferson County, Ky., died at his home in Lochland, April 6, after a long illness.

**Robert Q. Wilson, M.D.** Rush Medical College, Chicago, 1853, one of the wealthiest and most prominent citizens of Kokomo, Ind., died at his home in that city, March 31, aged 80.

**Charles N. Hayden, M.D.** University of Wooster, Cleveland, Ohio, 1866, the oldest practitioner of Lansing, Mich., died at his home in that city, April 7, after a lingering illness, aged 70.

**Carl Gottlieb Hirner, M.D.** Tübingen, Germany, 1853, died at his home in Allentown, Pa., April 4, from pulmonary tuberculosis, after a long illness, aged 67.

**Will C. Brumfield, M.D.** Washington University, St. Louis, Mo., 1877, of Porterville, Tulare County, Cal., died in San Francisco, after a short illness, April 4.

**J. W. Onstott, M.D.** University of Wooster, Cleveland, Ohio, 1885, died at his home in McKees Rocks, Pa., April 4, after a prolonged illness, aged 43.

**William Wood, M.D.** Castleton (Vt.) Medical College, 1852, a resident of Cairo, Ill., for half a century, died at his home in that city, April 5, aged 80.

**Henry Herbert Vinke, M.D.** Missouri Medical College, St. Louis, 1882, died at his home in St. Charles, Mo., from pneumonia, April 9, aged 42.

**Charles H. Berry, M.D.** University of Michigan, Ann Arbor, 1868, died at his home in Columbia City, Ind., March 28, from paralysis, aged 60.

**Alexander McCoy, M.D.** a prominent physician of Tazewell County, Ill., for nearly fifty years, died at his home in Pekin, April 2, aged 79.

**William E. Lee, M.D.** Memphis (Tenn.) Hospital Medical College, 1884, died at his home in Montcalm, Lincoln parish, La., April 1.

**Julius C. Pasley, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1878, died recently at his home in Arcadia, Kan., aged 52.

**James J. Pinckard, M.D.** Louisville Medical College, 1871, died recently at Beaumont, Texas.

## Miscellany.

### AN OPERATING TABLE.

THOMAS M. HOPKINS, M.D.

DENVER, COLO.

It may seem presumptuous in me to intimate that any improvement can be made in the operating tables used in our well-equipped modern hospitals. There is one criticism, how-

Figure 1.

ever, which I think is quite reasonable; to place a patient upon a cold glass or metallic table, saturate his clothing with

Figure 2.

water, and allow him to remain in this condition for an hour or more, appears to me to be subjecting him to an unnecessary

Figure 3.

and dangerous exposure. I have devised an appliance which will overcome these objections.

The accompanying drawings illustrate how a table can be

made which will furnish a warm surface for the patient to lie upon during the operation.

Fig. 1 shows side view of the table. *a*, Represents a reservoir attached to the table upon which the glass slabs will lie. The reservoir is to be made water tight and filled with warm water. *b*, Represents the drip trough underneath. *c*, Represents the inlet which is controlled by a funnel through which water can be poured by means of a funnel. *d*, Is the outlet also controlled by a cock. *e*, Represents a thermometer placed inside the reservoir with a small glass window at the side, so that the temperature of the water may be readily seen.

Fig. 2 represents top view of the table, showing the reservoir underneath the glass slabs, *f*, upon which the patient will lie.

Fig. 3 represents cross section of the table showing the reservoir in position; *f*, represents the glass slabs resting directly upon the reservoir, the slot between them allows the fluids to flow into the drip trough *b*, which can be withdrawn and cleansed.

Fig. 4 represents enlarged detail section of the reservoir and the manner in which it is secured to the frame of the table.

The reservoir may be made of aluminum, copper or any other suitable material. It can be applied to any table by making a few alterations. If the water in the reservoir becomes cold, a small amount can be withdrawn and hot water added

Figure 4.

in sufficient quantity to raise the temperature of the water as high as desired. To maintain the heat of the water an alcohol lamp or a gas jet may be placed under the reservoir during the interval between operations.

In representing my idea by these drawings, I have used the frame of the Baldwin table, as its construction is simpler than any other one with which I am familiar. I invite the criticism of the members of the profession upon this appliance, and if, in the opinion of these competent to judge, it has merit, I hope an early day will see it adopted into general use.

2710 E. 12th Ave.

## Association News.

### Conference of the Committee on National Legislation of the American Medical Association.

The third annual conference of the Committee on National Legislation of the American Medical Association was called to order by the chairman, Dr. H. L. E. Johnson, at 9 a. m., April 10, at the Arlington Hotel, Washington, D. C. Twenty-four members were present. Dr. Emil Amberg, chairman of the Committee on Uniform Legislation on basis of uniform medical education, presented a report which was discussed very generally and after slight modification was unanimously adopted and approved, and on motion was referred to the House of Delegates at the Saratoga meeting. The Committee

on State Medical Organization, Dr. Shinault, chairman, made a report of the work of that committee since the last conference. The report was further discussed by Drs. Bracken, Goff and others. The death of Dr. L. B. Tuckerman of Cleveland, Ohio, was announced, and Dr. Amberg was appointed a committee to draw up suitable resolutions of regret, which, on presentation, were adopted. The Committee on National Legislation made a report of its work *ad interim*, and made many recommendations, which, on motion, were approved by the conference. The official action of the Conference of State Health Officers at Washington, March 12-13 last, and their recommendations to Congress and this conference, on the several pending National Health Bills were considered and approved. They recommend the adoption of the Perkins-Hepburn Bill, with the following amendment to Section 7, "That when, in the opinion of the Surgeon-General of the United States Health Service, the interests of the public health would be promoted by a conference with the state or territorial boards of health or health authorities, the District of Columbia included, the Surgeon-General of the United States Health Service may, or, on the application of five state boards of health or quarantine officers, he shall invite representatives of state boards of health, and the quarantine officers to send delegates—not more than one from each state and territory and District of Columbia—to said conference."

A committee of three, consisting of Drs. H. L. E. Johnson, Wm. H. Welch and Wm. H. Rodman, was appointed to wait upon the committees in Congress having charge of the bill, and urge its passage with the proposed amendment. (The committee conferred with Senator Spooner and complied with the instructions of the conference.) The conference took up the consideration of Senate Bill 189, providing for the further prevention of cruelty to animals in the District of Columbia, recommending adverse action by Congress. Dr. Welch presented resolutions against the adoption of the bill, and he was appointed a committee of one to present these as the sense of the conference to the House and Senate. Favorable action was taken on the Nelson Bill to establish the Department of Commerce and Labor; the Proctor Bill to provide for the payment of medical expenses of sick officers and enlisted men of the Army while absent from duty with leave or on furlough, and the amendment to Section 18 of Act 4300, the Army Reorganization Bill, as proposed by Dr. John J. Riley, U. S. A., of the Legislative Committee of the Medical Officers of the U. S. A. at Manila, Philippine Islands. The report of Surgeon-General George M. Sternberg, ex-president of the American Medical Association, on Army Medical Reorganization was received with applause and adopted unanimously. Reports were received and Dr. Marmion, representing the Medical Department of the United States-Navy, Dr. Salmon, the Bureau of Animal Industry, and the delegate from each state medical society represented, all of which received the unanimous approval of the conference. To carry out the expressed wishes and various resolutions of the American Medical Association, the following was presented by the Committee on National Legislation, unanimously adopted by the conference with instructions to the same committee to present the matter to Congress and secure its passage.

On June 7, 1899, the American Medical Association approved the following resolution:

WHEREAS, The position of Surgeon-General of the United States Army involves great and grave responsibility, the direction of vast interests, the highest order of professional skill and learning and executive ability; and

WHEREAS, The number of officers and soldiers under the direction of the Surgeon-General in an army organized as is the Army of the United States is greater than the command of a division commander, be it

Resolved, That it is the sense of this body that the Surgeon-General of the Army should have the rank, pay and allowances of a major-general.

The officer who was Surgeon-General at the time this resolution was passed was Brig.-General George M. Sternberg, whose period of forty-one years' service will expire June 8, 1902.

General Sternberg entered the Army May 31, 1861, at the beginning of that momentous period in the history of our country, and served throughout the war of secession—for the most part in the field—where he rendered valuable and efficient

service, for which he received honorable mention and brevet rank. Subsequently, for many years, he served on the frontier and in several Indian expeditions, where he added to the reputation already gained.

General Sternberg early appreciated the enormous importance to humanity that would result from the scientific development of the germ theory of disease, to which he devoted himself so assiduously and with such success that his name is recognized throughout the world as one of the pioneers in the science of bacteriology, his works on that subject being among the most valuable extant.

General Sternberg was appointed Surgeon-General of the Army May 30, 1893. He immediately devoted himself to the advancement of his corps along scientific lines with which he was so familiar. He at once organized the Army Medical School, wherein the recently appointed officers of the corps are instructed in the special subjects most important to the successful performance of their work. He established at every permanent post a bacteriologic laboratory and demanded that the professional work of the corps be advanced to the highest plane. During the first five years of his incumbency he exerted every effort to place his corps in a position to meet the exigencies of war. Before assuming the office of Surgeon-General he had already qualified himself by experience in every field that a medical officer could be called upon to explore, and by the deepest study of the causes of disease to undertake the direction of the most difficult department of the Army. Through his persistent efforts the beginning of the war with Spain found the personnel of his department ready to meet the demands of active service to the full limit of the Army for which it was organized. When this war was declared he immediately proceeded, amidst great legislative embarrassments and administrative obstacles, to organize a medical department from the civil profession to meet the demands of a new army of 250,000 men.

"The enormous addition to his labors, due to a sudden multiplication of a combatant force by ten, and the final retention of the permanent strength at four times the antebellum number, has been met by him readily and easily, performing duties many times more arduous and responsible than those of a major-general (except only the Commanding General in the Division of the Philippines), and he has remained a brigadier-general, although the medical profession of the country has unanimously urged the advancement of the surgeon-generalcy to the grade of major-general."

A glance at the functions of the Medical Department of the Army will convince any unprejudiced person of the enormous responsibilities attaching to its chief. They are:

First. To investigate the sanitary condition of the Army and make recommendation in reference thereto.

Second. To care for the sick and wounded.

Third. To make physical examinations of officers and enlisted men.

Fourth. To manage and control military hospitals.

Fifth. To recruit, instruct and control the Hospital Corps and Nurses' Corps.

Sixth. To furnish all medical and hospital supplies for the department.

It will be observed from the foregoing that the responsibilities of the Surgeon-General attach primarily to men (secondarily, to material). He has control of, and is responsible for, the sick of the entire army and the personnel necessary to their care.

Assuming that the sick number 7 per cent. and the personnel 5 per cent., it is seen that 12 per cent. of our army constitutes the command of the Surgeon-General. With us to-day that means a responsibility for twelve thousand men, which is about the equivalent of a division. But aside from these twelve thousand men, the functions of the Surgeon-General extend widely beyond that of a major-general of the line, for he has advisory supervision of the sanitary condition of the entire army. He must direct the examination of every recruit who enters the service, and of every man who is discharged for disability; of every officer at entrance, promotion, etc. He must recruit, instruct and discipline the Hospital Corps—a body of nearly 5000 men. He must organize, super-

wise and direct the administration of all military hospitals and he must purchase the medical and surgical material necessary for the service. No other officer in the army combines the dual function of control of personnel and the supply of material as is done by the Surgeon-General, and no other officer has the responsibilities that attach to him.

We need not go afield in civil life to seek comparisons between the responsibilities of this office and those of the captains of industry, but it is not hard to imagine that the amount of executive capacity and actual work demanded of the head of the medical department could not be obtained in civil life for five times the remuneration which he receives. In other armies, where the responsibilities of the surgeon-general are often less than our own, he is given a much higher rank: in the British service, that of a lieutenant-general; in the German and French services, a major-general. In fact everywhere the importance of the office and the dignity attaching to it are recognized by rank, without which no military office can be effective.

General Sternberg's military services have been so important, so devoted, that his appointment as Major-General would be but just recognition thereof. This certainly should be done as a mark of appreciation by his country of his services as a soldier.

His accomplishments as a scientific and professional man are already a part of the history of modern medicine, and his work for humanity is honored by all the world. Congress can not add to this physician's honors, but through it the country can give material recognition of its debt to one who has worked far beyond the ordinary measure for its welfare. Congress can reward the head of the Medical Department of the Army and through him recognize the great work of a devoted corps, to which praise has come sparingly and material reward not at all.

In view of the foregoing we, the representatives of the American Medical Association, respectfully submit to Congress the following bill, the adoption of which is earnestly recommended:

*Be it enacted by the Senate and House of Representatives of the United States of America, in Congress Assembled, That the President of the United States is hereby authorized to select one from the medical officers of the Army, who has served forty-one years or more, nine years of which as surgeon-general, and by and with the advice and consent of the Senate, appoint him a Major-General of the United States Army for the purpose of placing him on the retired list.*

**Hotel Rates.**—The Kensington Hotel rates, appearing in the issue of April 12, should be for single rooms \$3 to \$4, and for double rooms \$6 to \$8 per day.

**American Medical Association Membership.**—Two hundred and fifty-eight new members of the A. M. A. are reported by THE JOURNAL for the month of January. Not one new member from Minnesota! What is the matter with our medical men? South Dakota sent in 6 new names, North Dakota 2, Wisconsin 6, Iowa 4, and California 30. Dr. Wyeth, the new president, in a circular letter urges medical men to join the "only representative National organization in the Union," the one great aim of which is to federate into one compact organization the medical profession of the United States. Its comprehensive scheme embraces the formation in every county of a medical society, with a uniform constitution and by-laws, each of which shall belong to the state association, organized and governed with equal uniformity, and all a part of the National body. Of course it is expected that difficulties may arise in counties or states where societies are few and at too great a distance for medical men to attend. Such matters will be adjusted in time by the formation of new county societies or the eligibility of men to societies in adjoining counties. These possible delays should not prevent men in populous counties where societies already exist from joining the Association. Let our Minnesota medical men bend every effort to affiliate with a society, and send in applications for membership to the A. M. A. that Minnesota may make a good showing before the meeting at Saratoga.—*Northwestern Lancet.*

## Societies.

### COMING MEETINGS.

American Medical Association, Saratoga Springs, N. Y., June 10 to 13.  
 Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.  
 Association of American Physicians, Washington, D. C., April 29 to May 1, 1902.  
 American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.  
 International Association of Railway Surgeons, St. Louis, Mo., April 30 and May 1 and 2, 1902.  
 American Gastro-Enterological Association, Washington, D. C., May 2, 1902.  
 Nebraska State Medical Society, Omaha, May 6-8, 1902.  
 Texas State Medical Association, Dallas, May 6-9, 1902.  
 Kansas Medical Society, Lawrence, May 7-9, 1902.  
 American Therapeutic Society, New York City, May 13, 1902.  
 Utah State Medical Society, Salt Lake City, May 13-14, 1902.  
 Oklahoma Territory Medical Association, Oklahoma City, May 14, 1902.  
 Arkansas Medical Society, Little Rock, May 13-15, 1902.  
 New Hampshire Medical Society, Concord, May 15-16, 1902.  
 Illinois State Medical Society, Quincy, May 20-22, 1902.  
 American Surgical Association, Albany, N. Y., May 20-22, 1902.  
 Medical Association of the State of Missouri, St. Joseph, May 20-22, 1902.  
 Kentucky State Medical Society, Paducah, May 7-9, 1902.  
 Arizona Medical Association, Tucson, May 21-22, 1902.  
 Medical Society of West Virginia, Parkersburg, May 21-23, 1902.  
 Medical Association of Montana, Anaconda, May 21-22, 1902.  
 Iowa State Medical Society, Des Moines, May 21-23, 1902.  
 Indiana State Medical Society, Evansville, May 22-23, 1902.  
 American Pediatric Society, Boston, May 26-28, 1902.  
 American Laryngological Association, Boston, Mass., May 26-28, 1902.  
 American Gynecological Society, Atlantic City, May 27, 1902.  
 Connecticut Medical Society, New Haven, May 28-29, 1902.  
 Ohio State Medical Society, Toledo, May 28-30, 1902.

**Rappahannock Valley (Va.) Medical Society.**—This Society held its annual meeting at Fredericksburg, Va., March 27, and elected Dr. J. Edward Tompkins, Fredericksburg, president.

**Lyons County (Kan.) Medical Society.**—This Society held its annual meeting at Emporia, April 1, and elected Dr. Thomas F. Fonnannon, president, and Dr. Jonathan J. Wright, vice-president and treasurer.

**Terrell (Texas) Medical Society.**—On March 28, this Society held its annual meeting and elected Dr. William H. Neely, president; Drs. Thomas B. Bass and Samuel M. Gladney, vice-presidents, and Dr. James Orr, secretary.

**Butte (Mont.) Medical Society.**—This Society was organized, April 6, with the following officers: Dr. Havelock H. Hanson, president; Dr. Thompson G. Heine, vice-president; Dr. Thomas B. Moore, secretary, and Dr. Willis H. Haviland, treasurer.

**Henry County (Tenn.) Medical Society.**—At a meeting of this Society, at Paris, April 7, the following officers were elected: Dr. Felix F. Carter, president; Dr. Richard A. Grainger, vice-president, and Dr. John H. McSwain, secretary and treasurer, all of Paris.

**Orange County (Cal.) Medical Association.**—At its annual meeting, April 4, Dr. James P. Boyd, Santa Ana, was elected president; Dr. William Freeman, Fullerton, vice-president; Dr. John L. Dryer, Santa Ana, secretary, and Dr. Charles D. Ball, Santa Ana, treasurer.

**University of Texas Medical Club.**—This club was organized, January 6, and will meet monthly. The following officers were elected: Dr. James E. Thompson, president; Dr. John T. Moore, vice-president; Dr. William Kieller, secretary-treasurer, and Dr. William S. Carter, recorder.

**New London County (Conn.) Medical Association.**—The annual meeting of this organization was held at New London, April 3. Dr. Newton P. Smith, Norwich, was elected president; Dr. Harold H. Beyer, New London, vice-president, and Dr. Morton E. Fox, Montville, clerk and treasurer.

**Medical Association of the District of Columbia.**—At a meeting of this Society, held April 1, the following officers were elected: Dr. George N. Aker, president; Drs. John R. Wellington and Edmund L. Tompkins, vice-presidents; Dr. Monte Griffith, secretary, and Dr. Frank Leech, treasurer.

**Iola (Kan.) Medical Society.**—The physicians of Iola met, March 31, and organized this Society, the membership of which is to be limited to the physicians of Allen County. Dr. Frank D. Teas was elected president; Dr. Wyatt, vice-president; Dr. Gantz, secretary, and Dr. W. H. McDowell, treasurer.

**Faulkner County (Ark.) Medical Society.**—The physicians of Faulkner County met at Conway, March 24, and organized a medical society, with the following officers: Dr. George D. Dickerson, president; Dr. Charles H. Voris, vice-president, and Dr. Joseph S. Westfield, secretary and treasurer, all of Conway.

**Waynesboro (Pa.) Academy of Medicine.**—This organization, which was established in 1884, flourished until 1890, and since that time has been inactive, was reorganized, April 4, with the following officers: Dr. James B. Amberson, president; Dr. A. B. Sollenberger, vice-president, and Dr. Percy D. Hoover, secretary and treasurer.

**Denison (Texas) Medical Association.**—The physicians of Denison met, April 3, and organized a society, with an initial membership of seventeen. Dr. Ashel B. Gardner was elected president; Dr. Pierre Wilson, vice-president; Dr. D. Ross, secretary; Dr. John M. Owensby, corresponding secretary, and Dr. Daniel H. Bailey, treasurer.

**Golden Belt (Kan.) Medical Association.**—This Society, whose membership is made up from the physicians of Central Kansas, met at Abilene, April 4, and elected Dr. John C. McClintock, Topeka, president; Dr. John T. Curtiss, Dwight, secretary, and Dr. Cassius W. Brooks, Enterprise, treasurer. The next meeting will be held at Chapman, in July.

**Pulaski County (Ill.) Medical Society.**—The annual meeting of this Society was held at Villa Ridge, April 1. Dr. Marcus L. Winstead, Wetaug, was re-elected president and Dr. Charles J. Boswell, Beechwood, secretary. The next meeting will be held in Mound City, July 1. It was decided to make Mound City the permanent meeting place and to hold meetings quarterly.

**Polk County (Iowa) Medical Society.**—The annual meeting, election of officers and banquet of this Society were held, April 1. Dr. Charles D. Rawson was elected president; Dr. Edith G. Fosnes, first vice-president; Dr. Granville N. Ryan, second vice-president; Dr. Lenna L. Means, secretary, and Dr. William S. Conklin, treasurer, all of Des Moines. Dr. Michael F. Patterson, Des Moines, presided over the banquet as toastmaster.

**Association of House Physicians of Harper Hospital (Detroit).**—Ex-internes and members of the present house staff of Harper Hospital, to the number of 21, met at the hospital, April 3, for organization. The following officers were elected: Dr. Henry O. Walker, president; Drs. Howard W. Longyear, John K. Gailey, and Frederick W. Robbins, vice-presidents; Dr. F. R. McClure, secretary, and Dr. Richard T. Mason, treasurer, all of Detroit.

**Clark County (Ohio) Medical Society.**—At the regular meeting of this Society, at Springfield, April 3, Dr. John H. Rodgers delivered an address on the "Reorganization of the Medical Societies." He believes in the reorganization as laid down by the American Medical Association, that is, a reorganization from the county societies to the national association on a uniform basis. The general principle involved is the putting of the Society on a better basis for scientific and literary work, and for anything which pertains to the advancement of the profession.

#### TENNESSEE STATE MEDICAL SOCIETY.

*Sixty-ninth Annual Session, held at Memphis, April 8-10.*

President, Dr. Deering J. Roberts, Nashville, in the Chair.

##### Address of Welcome.

This meeting was a profitable and interesting one and was well attended. Among the visitors were Drs. Frank Billings and Fenton B. Turk, Chicago; Edwin S. Ricketts, Cincinnati; J. N. MacCormack, Bowling Green, Ky., and P. W. Rowland, Oxford, Miss. The meetings of the Society were held at the Peabody Hotel.

The address of welcome was delivered by Dr. E. M. Holder, who referred to the great work done by physicians and surgeons from the earliest times for the sake of science. In conclusion he said: "It seems to me that the most beautiful benediction of the medical profession has descended upon the poor. There is no excuse now for anyone not receiving scientific treatment. All over the civilized world there are dispensaries and hospitals under the control of the very best doctors. A half-starved woman comes out from her low tenement house into the dispensary and unwraps the rags from her baby and over the little sufferer bands the accumulated wisdom of ages.

In one dispensary in one year 150,000 prescriptions were written. Who will say that anesthesia is not of greater benefit to the world than all the poetry that was ever written? Or that asepsis in the operating room does not represent a greater wealth of service than has been rendered by all the artists and novelists who ever trod the earth? Long may such achievements live in song and story to inspire countless generations of youths yet unborn with love for the science of medicine and surgery."

##### Dr. Billings on Cirrhosis.

After Dr. S. R. Miller, Knoxville, responded in brief and appropriate terms to the address of welcome and the committee on arrangements reported, the first feature on the official program was the special address by Dr. Frank Billings on "Symptoms and Signs from the Early Stages of Cirrhosis, with Report of Cases." The paper was one of the most learned and instructive treatises that has been presented before the Society and was discussed by Drs. Henning, Frank Jones of Memphis, Cowan of Tullahoma, Shedd of Columbia, and Fenton B. Turk of Chicago.

##### Pneumonia.

DR. G. B. HENNING, Memphis, read a paper on "Pneumonia." His conclusions are that the mortality from this disease has not decreased with the advance of medical science. He regretted that no routine treatment could be offered for this disease, and advised that the patient be treated as the symptoms developed.

DR. DEERING J. ROBERTS, Nashville, praised creosote in the treatment of pneumonia.

DR. REAGOR, Shelbyville, believes that the death-rate from pneumonia was higher now than in the days of venesection, and furthermore believes that bleeding would yet be recognized as an important feature in the treatment.

In closing the discussion Dr. Henning stated that there were only two anatomic conditions to deal with in pneumonia. When the disease attacked the air passages it became catarrhal and was likely to be protracted and the contrast between the mortality of pneumonia in the city and country was very marked, the mortality being much higher in the country despite the fact that the patients were, as a rule, more robust. He agreed with the last speaker that the lancet was often efficacious.

##### Gunshot Wounds of the Stomach.

DR. PAUL F. EVE, Nashville, reported a case of gunshot wound of the stomach. The surgeon should exercise the greatest care in these cases in searching for wounds of the stomach, as almost invariably two punctures will be found. The stomach should be dilated for thorough examination and sutured. No nourishment should be allowed in the stomach for at least three or six days, then nothing but liquids. He never allows solids or any food capable of fermentation to be given until eighteen or twenty days after the operation.

##### President's Annual Address.

At the evening session Dr. J. B. Murfree, Jr., first vice-president of the association, occupied the chair. The president, Dr. Deering J. Roberts, delivered his annual address. He outlined the histories and deeds of former presidents of the Tennessee Medical Society from 1830 to the present time. He cited the fact that through the association and its members much beneficial medical legislation has been secured, and mentioned that the society was more than 15 years older than the American Medical Association, and three of the members of the former society have been elected president of the national organization. He paid a tribute to the generation of young practitioners who, he stated, are the control spirits of the day and are superior to the former generation as they have better advantages, better opportunities and in addition the experience of their predecessors to help them. During the year the number of affiliated local and county societies was increased from 14 to 21.

##### Controversy Between Two County Societies.

The Judicial Committee, to which has been referred the controversy between the Shelby County Medical Society, a recently organized society and the Memphis and Shelby County Medical Society, reported in favor of the latter society, which has long

been affiliated with the state organization under the name of the Memphis Medical Society and has complied with all the requirements of the state and American Medical associations. The societies of Lincoln and Hardeman counties were also recognized and the recognition of the societies of Overton and Lauderdale counties were deferred until certain amendments should be made to their constitution and by-laws.

#### The Hippocratic Oath.

DR. J. H. PRESTON, Humbolt, advocated that the profession should reaffirm its loyalty to the Hippocratic oath. He feared that too much commercial spirit was creeping into the profession, and appealed for a higher regard for medical ethics. He stated that there should be in the ranks of the profession the system of freemasonry whereby the differences and friction of the members might be kept a secret from the laity, and closed with an earnest appeal for the adherence to the Code of Ethics.

#### Pathologic Tonsils.

DR. RICHMOND MCKINNEY, Memphis, read a paper on "Pathologic Tonsils with Some Considerations of Treatment," in which he said that the prejudice against the removal of tonsils was born of ignorance. He strongly advocated the operation and described in detail the symptoms and treatment of the various diseases of the tonsils and of the operations for their removal. His observation has been that the range of the singing voice is greatly increased rather than injured by the removal of the tonsils.

#### Dr. Turck on Gastro-Enteroptosis.

The second day's session, April 9, opened with a paper by Dr. Fenton B. Turck, Chicago, on "Gastro-enteroptosis," in which he illustrated the various stages of the disease by large x-ray photographs, and described the modern methods of diagnosis and treatment.

#### Smallpox and Mercury Bichlorid.

DR. E. W. RIDINGS, Dickson, presented a paper on "Bichlorid of Mercury in the Treatment of Smallpox." In the portion of the state in which Dr. Ridings resides there appears to have been a special susceptibility to smallpox, and he has almost limitless opportunities for observation and treatment. He described his method of treatment of the disease by bichlorid of mercury baths and asserted that the specially low mortality of the patients was due, in some measure at least, to this treatment.

#### Adoption of the New Constitution and By-Laws.

At the afternoon session, the Judicial Council reported that it had given careful consideration to every section of the new constitution and by-laws, and each section had been unanimously adopted. They were practically the same as those adopted by the American Medical Association and conformed to all the requirements of that body. After considerable discussion the constitution and by-laws were adopted as a whole.

#### Necrology.

The Necrology Committee reported that since the last meeting of the society the following men had died: Dr. R. L. Bush, Gallatin, graduated from the University of New York in 1865; Dr. William L. Nichol, Nashville, University of Pennsylvania, in 1849; Dr. E. P. Sale, Memphis, Tulane University, 1869; Dr. B. W. Stone, Louisville, Ky., Kentucky School of Medicine, 1868; Dr. Charles William Beaumont, Clarksville, University of Pennsylvania, and Dr. Asa Bell, Henderson. The report of the committee was accompanied by an eloquent and feeling tribute to the memory of the late Dr. Beaumont, written by Dr. C. W. Runyon of Clarksville.

#### Medical Examiners and Board of Health.

The resolution was unanimously adopted that the society have the Governor appoint Dr. T. J. Happel, Trenton, a member of the State Board of Medical Examiners for the western division of the state.

The resolution offered by the Secretary that it be the sense of the society that the medical members of the State Board of Health be appointed from members affiliated and in accord with the State Medical Society was enthusiastically adopted.

#### Injuries of the Tarsus.

DR. T. J. HAPPEL, Trenton, read a paper on "Injuries of the Tarsus, with Reports of Three Cases." He took the position that no wound or puncture of the foot, however trivial, should be neglected. Even if it were a mere scratch, it was worthy of the most careful surgical attention and aseptic treatment; if this care were taken cases of tetanus would be less frequent.

#### Treatment of Pelvic Lesions.

DR. EDWIN RICKETTS, Cincinnati, read a paper on "Diagnosis and Treatment of Pelvic Lesions," in which he paid an eloquent tribute to the distinguished physicians of the South. The scientific portion of the paper provoked a spirited discussion, in which Drs. McGarnon of Nashville, Crawford of Memphis, Burch of Nashville, Haggard of Nashville and Sheddan of Columbia entered.

#### April 10—Morning Session.

In the election of officers, Dr. S. R. Miller, Knoxville, was made president; Dr. Cooper Holtzelaw, Chattanooga, vice-president; Dr. F. J. Runyon, Clarksville, third vice-president; Dr. Deering J. Roberts, Nashville, secretary; Dr. W. C. Bilbro, treasurer; Dr. W. F. Glenn, Nashville, delegate to the American Medical Association, and Dr. B. C. Savage, alternate.

The society adjourned to meet in 1903 in Nashville.

### SEMI-CENTENNIAL MEETING OF CHICAGO MEDICAL SOCIETY.

*Celebrated April 9, 1902, at the Auditorium Hotel.*

Dr. Alexander Hugh Ferguson, in the Chair.

#### Etiology and Spread of Typhoid Fever.

DR. VICTOR C. VATGHAN, Ann Arbor, Mich., delivered an address on this subject, which appears in this issue.

#### Organization of the Medical Profession.

DR. J. T. MCANALLY, Carbondale, Ill., president of the Illinois State Medical Society, in this address, said the time had come when medical societies must enlarge their scope of usefulness. Medical men are coming to believe that the scope of medical societies is too narrow. We can no longer ignore the material and social interests of the members, if we are to keep a compact organization. There are many subjects for medical societies to discuss other than strictly scientific matters, such as irregularities in practice, the best means of obviating them and the prosecution of offenders against the medical statutes.

#### Fifty Years of the Society.

DR. N. S. DAVIS, Sr., gave brief reminiscences of the origin and growth of the society. He referred to two or three critical periods in its existence. He said, when the society was first organized, and during the three or more years of the beginning of its existence, the profession was in a condition of entire disorganization as far as harmony was concerned. There were more physicians in proportion to the population than there were now. One of them had a wide reputation for dealing in thunder and lightning pills, and some of the members of the profession devoted more time to dealing in real estate and politics than to the practice of medicine, consequently they could not be induced by any influence to pay any attention to the organization of the profession at that time, and they had to be left out. Of the rest, they were divided into factions, each group worked for its own end and fought the other groups. The most influential group was connected with a medical college that had been planted here, and there was a bitter enmity on the part of two or three of the minor groups against those that belonged to the college. After speaking of the different crises through which the society had passed, to show the way in which physicians were divided into warring factions when Chicago was young, he related the story of a man whose leg had been nearly torn off in a street accident. Several physicians of one clique had made preparations to amputate the limb where the accident happened, when another faction arrived and succeeded in driving the first lot away from the patient. Dr. Davis said there was less bickering and less enmity among members of the profession in Chicago to-day than in any other

city in the United States: he hoped that this good, cordial, liberal feeling one with another would be cultivated until the end of time.

He thought there was such a thing as having too many organizations, too many things to attend. He said he had heard of doctors in Chicago who were attached to so many hospitals that it seemed to him if they visited each one during the week they would accomplish nothing else. He urged the members of the profession to be a little cautious. If they wanted to accomplish the most there was in this life, they should select their field of labor and cultivate it, but not try to cultivate all the earth.

In closing, Dr. Davis said that his work was nearly over and he found that he could do only a little every day and then rest in his comfortable home and wait for the end of life to come. He was happy that he had lived so long and had seen the growth of the society from its small beginning to the present membership of between ten and eleven hundred.

DR. J. N. DANFORTH, one of the older members of the society, gave a number of reminiscences of the early days and the different methods of practice then in vogue.

DR. FRANK BILLINGS followed with remarks in which he paid an eloquent tribute to the late president, Dr. Christian Fenger. Among other things, he said that Fenger's knowledge of pathology made him a surgeon. He was not an operator. There was a distinction between a surgeon and an operator. Almost any physician could be an operator, but surgeons were few, and Fenger was one of them. He was a man who knew when a case was operable and when it was not and he did not operate unless the indications demanded it. He undertook the most difficult operation and never stopped when he once began. Although slow as an operator, his results were as good, if not better, than the most brilliant operators who have ever wielded the knife.

## CHICAGO SOCIETY OF INTERNAL MEDICINE.

*Regular Meeting, held March 31, 1902.*

President, Dr. Edward F. Wells, in the Chair.

DR. CHARLES SPENCER WILLIAMSON read a paper entitled "Muscular Mitral Insufficiency," which will appear in THE JOURNAL.

### The Prognosis and Treatment of Suppurative Pleurisy.

DR. E. FLETCHER INGALS read a paper with this title, giving an analysis of eighty-three cases taken from his own records and those of the Presbyterian and Cook County Hospitals.

The prognosis in empyema had always been considered unfavorable, and it became interesting to inquire how far this had been modified by the progress of surgery in recent years. Laennec, writing in 1826, conveyed the impression that very few cases recovered, either with or without operation. Alfred L. Loomis stated that the majority of empyemic children recover, while in adults, although for a time there is improvement, it seems that phthisis is almost certain to develop sooner or later. The essayist was unable to obtain accurate statistics of cases left entirely to nature, or to medicinal treatment, but all of the authors at his command agreed that if left to themselves nearly all die.

Operative treatment changes the prognosis decidedly, fatality now being the exception in uncomplicated cases that are properly treated early.

Puncture with a trocar through the canula in which a double tube was introduced and brought out with the end under water was recommended by Kussmaul in 1869. Without knowledge of Kussmaul's recommendation, Dr. Ingals has used this method in most of his cases since 1872; but for the past ten years he has employed a trocar so large that two drainage tubes, each with a caliber of three-sixteenths of an inch, could be passed through it. A tube of this size is so large that it obviates most of the objections which were properly urged against the tubes that were employed when this method was first introduced.

The advantages urged for the drainage tubes are that they

enable one to secure free drainage and to wash out the cavity thoroughly, and if introduced through a trocar in the proper manner, they exclude air for ten or twelve days, during which time the lung will have expanded and the chest wall contracted to a great extent and adhesions will have taken place between the pleural surfaces, so as to diminish materially the size of the suppurative cavity.

After giving the statistics of numerous authors, Dr. Ingals states that of his own cases, all but one of which were operated on by introducing a drainage tube through a trocar, six were of less than four weeks' duration and all of these recovered; fourteen were of from two months' to three years' duration and of these only 9 recovered. In other words, 100 per cent. recovered in early cases, and only 64 per cent. in those of longer duration.

In pleurotomy difference of opinion exists as to whether it is better to make the opening small or large. If the pus has already escaped between the ribs and is burrowing under the skin, Wilson Fox recommends that a valve-like opening be made through the skin and the knife not allowed to penetrate the thoracic cavity, thus preserving nature's method. But under other conditions exsection of one or two ribs is desirable in order to scrape out the fibrinous deposit.

Of the 83 cases that he is considering, 41 were operated upon by exsection of a portion of one or more ribs, and of these only 12, or 30 per cent., recovered. Of those that recovered, 2 were in children, whom it has been shown usually recover under almost any form of treatment, and 4 were in those over 15 years of age, who had not been sick for more than a month when the operation was done. In 11 cases the disease had been present for several months, and of these 2 recovered, 2 were improved and 7, or 64 per cent., died.

Exsection of the rib is easily performed, and wherever the intercostal spaces are greatly narrowed by retraction of the chest, as when there has been perforation of the lung so that the pus has been continually escaping, this operation is the only one to be recommended. In acute cases where retraction has not taken place, he believes that the introduction of the double drainage tube through a canula and the exclusion of air for several days after the operation very considerably improves the patient's chances for life, for although exsection of a rib is easy, the danger of secondary infection, especially through the cut ends of the rib, is considerable, and the operation is much more formidable than by the trocar.

Being fully convinced of the advantages of the operation by the trocar, he urged it in all suitable cases, which comprise nearly all of the empyemas in children and the great majority of cases in adults in whom the disease is not of more than two or three months' duration. In these 83 cases, which were taken in order without any selection, of those operated upon by the method he recommends, 70 per cent. recovered, while of those in whom exsection of a rib was done, only 30 per cent. recovered.

Dr. Ingals then gave the directions for the operation and the subsequent treatment at considerable length.

DR. EDWARD F. WELLS warned against the free use of peroxid of hydrogen in the chest cavity without free exit. He also mentioned an old case of left-sided empyema in which the spleen was greatly enlarged. One day in dressing the cavity and pressing over the spleen he noticed fluid pouring out of the opening freely; whereas, if he relaxed the pressure air entered. Applying an elastic bandage around the chest and forcing the spleen up a little, little was required to expedite a cure. In two or three weeks the cavity had closed because the surfaces were coaptated properly.

DR. JOSEPH M. PATTON said that the age of patients had a good deal to do with the mortality. Then, we must remember the cause of death in those cases which were due to general infection and embolism, causes which might act in various cases irrespective of the nature of the operation. In regard to the selection of the operation to be performed, too much stress could not be laid on the nature of the infection. He spoke of three or four cases that had recovered from simple aspiration. Some time ago he aspirated a boy the ninth time. He was aspirated twice afterwards; he saw the boy about a year subsequently and his recovery was perfect. However,

he did not think we could rely too much on aspiration. Surgeons taught that nothing would do short of exsection of a rib. He believed this to be good teaching in chronic cases, but not in acute, especially in pneumonic affections, as a large percentage of such cases could be cured by simple siphon drainage. He had drained three or four cases with single siphon drainage with satisfactory results. One of these patients, a child of 6 years, recovered in six weeks, and the loss of expansion on the affected side two years afterwards was less than one-quarter inch. He uses the single tube because he does not believe that in very recent cases of pneumococcus infection irrigation is necessary or advisable.

DR. WESSELS, of Cape Town, South Africa, expressed himself as being conservative with reference to operating on acute cases of empyema. Even before resorting to aspiration it was necessary to weigh the matter very carefully, lest one disturbed the condition of the patient. Operations which caused the prolapse of one side of the thorax by removing a number of ribs to close a chronic cavity which had existed for a long time were indicated in order to cure intractable cases of empyema; but in well-selected cases he thought aspiration would probably do as much good as the resection of one or more ribs.

DR. JOHN A. ROBISON said that prior to ten years ago he had performed the operation outlined by the essayist eleven times, and he reported 100 per cent. of recoveries.

DR. INGALS, in closing the discussion, said that his own experience had not been that many of the cases were tubercular. He did not recall any case, excepting that of an empyema, where there was pure pus that seemed to him to be tubercular. The cases that appeared to him to be tubercular were those in which he got sero-pus. He recalled that Dr. Bowditch told him of four cases he had had in which there was sero-pus, and all of these died. He recalled two of his own cases of a similar character, one of which died.

The suggestion of Dr. Wells not to use peroxid of hydrogen was timely. Personally, he had never used it. However, if a large opening was made, it might be used safely, but he had never tried it.

As to whether one should make the opening at the point nature usually selects or not, this was a matter of individual choice, and physicians and surgeons varied much in their choice. Some operators preferred to open near the angle of the ribs, others at the mid-axillary line, still others a little farther forward. He liked to make the opening on a line near the angle of the ribs, believing that better drainage could be secured.

Referring to aspiration, he thought it very important to resort to preliminary aspiration, not with the hope of curing the patient of empyema, but for the purpose of expanding the lung.

#### NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA,

*Regular Meeting, held April 1, 1902.*

President, Dr. Wendell Reber, in the Chair.

#### Treatment of Heart Disease.

DR. I. NEWTON SNIVELY read a paper entitled "A Brief Consideration of the Scientific Treatment of a Few of the Diseases of the Heart," in which he laid great stress upon the importance of an individual study of the general condition of each patient showing cardiac lesions, especial attention being directed to the condition of the kidneys. In the author's opinion no heart medicine is needed if the myocardium is able to perform its work in a satisfactory manner, and more consideration should be given to the heart muscle than to the heart murmur. Among the most important therapeutic agents in the treatment of cardiac conditions are rest in bed, properly selected diet and the use of tonics to restore the blood to its normal condition. Physical exercise and light gymnastics were also stated to be of value in properly selected cases. In treating the acute infectious diseases the importance of preventing myocardial weakness by medicines tending to eliminate the poisons from the system was noted and as heart stimulants to be used

in conjunction with rest, in cases where a weakness of the myocardium is manifest, strychnia, caffeine, digitalis and alcohol were recommended.

DR. JEDSON DALAND opened the discussion and remarked upon the weak action of the heart in typhoid fever, directing particular attention to the fact that in these cases the ordinary symptoms of cardiac weakness are not present, the conditions making the greatest impression on the observer usually being the feebleness of the muscular element of the first sound, which is particularly important, not only as indicating the general condition of the myocardium, but also the condition of the circulation and acts as an important guide to general medication. Rest, properly arranged massage and Swedish movements were recommended to stimulate the flow of the blood in the veins and thus produce a balance of circulation.

DR. THOMAS H. FENTON believed much valuable information could be gained in cardiac and vascular conditions by the working together of the ophthalmologist and the clinician, the ophthalmoscopic observations revealing many conditions of the arteries and veins which are valuable adjuncts to the physician in the treatment of his patient.

DR. HOWARD S. ANDERS considered that the most important factor in the treatment of cardiac disease was the condition of the myocardium, which is also, in his opinion, one of the most difficult of diagnosis. Regarding hypertrophy and dilatation of the heart, he felt that while these two conditions usually occur in conjunction, yet the greatest difference in the apparent general condition of the patient is observed, depending upon which of the two is predominating. As a rule when hypertrophy predominates, the patient remains in fairly good health, while the reverse is true where dilatation is the predominant factor. Attention was called to the importance of making a thorough physical examination in all cases, and particular stress was laid upon the position and character of the apex beat, the area of heart dulness and the character of the sounds of the heart and, in the event of any of these conditions being discovered at a time when the patient is under treatment for some other disease, preventive measures were recommended.

DR. SAMUEL WOLFE considered many cases of dilatation due to malnutrition, and inclined to the opinion that in many instances the physician is too hasty in insisting upon the patient quitting his occupation and limiting the amount of exercise. While there are no doubt a considerable number of cases where these directions are necessary, yet the speaker felt that in a far larger majority it was of much more importance to prevent worry and regulate the diet and unless the lesions had progressed pretty far he did not think the physician was justified in ordering cessation of all work. Methodical muscular exercise should be carefully regulated by the physician. The use of cold baths is of value and the cold sponge baths can be employed to advantage in almost all cases.

DR. W. E. ROBERTSON reiterated the opinion that the most important factor is the condition of the heart muscle. He remarked upon the value of the position of the apex beat as an aid in diagnosis and recommended, to locate the normal apex beat, the use of a line dropped from the center of the clavicle, instead of the nipple line, which varies more or less according to the age, sex, and health of the individual. The importance of preserving the balance of circulation was thought to be especially illustrated in children, where the same symptoms of cardiac disease are not found as in adults. Failing compensation in adults is usually accompanied in its inception with some cyanosis and edema, while in children neither of these conditions is common and, if present at all, exists only to a slight degree, the predominating symptoms in the latter class of cases being progressive pallor and asthenia. The belief was expressed that the continued use of digitalis would in itself produce hypertrophy, a case being cited in which the patient had used this drug continuously for twenty years prior to his death, at which time the organ weighed two and one-half pounds. While the value of calomel in right-sided heart failure was not discounted upon, yet the speaker felt that better results would probably be obtained from the use of phosphates and the salicylates.

DR. JUDSON DALAND made a few remarks with reference to the anatomic condition of the heart in mitral regurgitation (non-inflammatory) secondary to dilatation and the discussion was closed by Dr. Snively, who urged upon the members the importance of improving the general condition of patients suffering from cardiac disease.

#### DENVER AND ARAPAHOE COUNTY MEDICAL SOCIETY.

*Regular Meeting, held March 11, 1902.*

Dr. George B. Paekard, in the Chair.

##### Surgical Treatment of Chronic Nephritis.

DR. C. B. LYMAN, after referring to the scant literature on this subject, and especially to the papers of Dr. Edebohls, related the case of a patient who was well until the summer of 1900, when he began to have headache and loss of appetite. Edema of the genitals and legs followed, with puffiness under the eyes. In February, 1901, when admitted to hospital, he had attacks of vomiting and partial loss of vision. He was tapped four times for ascites and showed an enlarged liver and heart, with a mitral systolic murmur. Symptoms of uremic intoxication yielded to vigorous treatment. The urine contained albumen in large quantities, granular hyalin and fatty casts, free fat globules and epithelial cells in a state of fatty degeneration. The operation was performed February 21, 1902, and consisted of complete decapsulation of both kidneys. The stomach was washed out after the anesthetic (ether) was discontinued. Both kidneys were diminished in size by fully one-third. The capsule peeled off easily. The operation consumed one hour and fifteen minutes. Sixteen ounces of urine, containing no blood, were withdrawn per catheter during the twenty-four hours following the operation. The day following the operation the pulse and temperature rose and the patient died 56 hours after the operation.

The fatal termination of the case should not and will not deter him from operating on suitable cases. That the handling of the kidney does no injury was proven by the fact that the urine following the operation did not contain any blood. In the future he will endeavor to determine before the operation whether one or both kidneys are involved. This would in many cases obviate a bilateral operation. In connection with the subject he thinks two questions deserve careful consideration. The first is whether it is advisable to operate on both kidneys at the same time or whether it is not wiser to operate on one kidney at a time, allowing an interval of a month or more to elapse between the operations. The cases where cure was effected early, according to Edebohls, were those when the disease was unilateral. The second question is whether it is necessary to do a complete decapsulation or whether a sufficient collateral circulation could not be obtained by making a partial denudation, such as is made in nephropexy.

DR. T. M. BURNS exhibited a rare specimen of a fetal anomaly. The fetus was expelled six months after the patient's last menstruation. The fetus was 3½ inches long and was covered by the amnion as by tight. The deformities were many—a meningocele, talipes, absence of toes and all the abdominal viscera were outside the abdomen. There was no history of prenatal shock or of maternal impressions.

#### TORONTO CLINICAL SOCIETY.

*Regular Meeting, held April 3, 1902.*

##### Purulent Pericarditis and Empyema.

DR. K. McILWRAITH reported three cases of puerperal septicaemia treated with the antistreptococcal serum with one death.

DR. R. D. DUBOIF reported an interesting case of purulent pericarditis and empyema, with operation and recovery. This occurred in a boy of 7 years, who was admitted to the Children's Hospital with shortness of breath, cough, pain, lips cyanosed, extremities cold, but no edema. The abdomen was prominent, especially in its upper portion, and the umbilicus was protruded. Palpation revealed the lower border of the liver a finger's breadth below the umbilicus. The respiration

was almost entirely thoracic. The cardiac impulse could not be detected at all. By the x-rays it was ascertained that there was an enormous collection of fluid in the pericardial sac which was interfering with the cardiac action. Dr. George A. Peters operated and over thirty-six ounces of fluid were taken away. The cyanosis disappeared rapidly, even before the patient left the operating table. The heart was not very much displaced. The empyema followed and was treated successfully in the usual way.

#### NEW YORK ACADEMY OF MEDICINE.

*Meeting of the Section on Medicine, March 18, 1902.*

Dr. James K. Crook, in the Chair.

##### Acute Articular Rheumatism—Its Pathogenesis.

DR. HEINRICH STERN made some remarks on this topic. He took the ground that the microbic theory of the origin of rheumatism was not based on clinical facts. Because of the old theory of the acidity of the blood in rheumatism he had accurately estimated the blood alkalinity in a number of cases and had found no marked deviations from the normal. Similarly the urine, though often vaguely called "highly acid," when examined by acidimetry showed the acidity to be close to the normal. Attention was directed to the fact that in acute rheumatism and in only one other disease, i. e., pneumonia, were the urinary chlorids decidedly reduced.

##### Symptomatology and Diagnosis.

DR. LEONARD WEBER said that the onset of acute articular rheumatism was sudden and the disease was often fully developed in twenty-four hours. Monoarticular rheumatism was very rare. In very well-marked cases anemia quickly developed. A soft cardiac murmur at the beginning was common and was not due to endocarditis but to the fever and anemia. If, however, the murmur persisted after defervescence, the patient should be kept absolutely quiet in bed for several weeks. Endocarditis should be looked upon as a part rather than as a complication of rheumatism. Gonorrheal arthritis is monoarticular and does not respond to the salicylates. Acute osteomyelitis might occur in several places simultaneously, and thus be mistaken for rheumatism. In atypical cases of gout, a search for deposits of urates about the joints would sometimes aid in the diagnosis.

##### Complications and Sequelae.

DR. FRANK W. JACKSON gave his own personal experience in this field. He said that the principal complications of rheumatism were hyperpyrexia, delirium, coma and convulsions, tonsillitis, bronchitis, pneumonia, meningitis, pleurisy and inflammations of the other serous membranes and inflammation of the kidneys. True hyperpyrexia, i. e., a temperature of 105 or 106 F. and usually fatal, was not frequent in this locality. Delirium in young rheumatic subjects was often due to the use of the salicylates. Coma and convulsions he had not seen. Acute rheumatic iritis was occasionally met with. While there was a distinct relation between throat inflammations and rheumatism he was not sure that they were a part of that disease. Rheumatic meningitis must be very rare, as he had not seen it. Rheumatic pleurisy was fairly common, and was generally of a mild type and characterized by its dryness or by the rapid formation of adhesions. In his own experience pericarditis had not been a very frequent complication of rheumatism. In making this statement he excluded cases having pericardial friction, due to a plastic inflammation between the pleura and the external layer of the pericardium. It was quite common in acute articular rheumatism for a heart murmur to be alternately audible and inaudible on different days. Careful and extended observation had convinced him that some patients absolutely recover from a rheumatic endocarditis.

##### Prognosis and Treatment.

DR. WILLIAM H. THOMSON took up this topic. He described rheumatism as a microbic infection running its course in about six weeks. The salicylates were chiefly useful in controlling the pain. He had found an antecedent tonsillitis in nearly 25

per cent. of his cases of rheumatism and hence he favored, as a prophylactic measure, the douching of the throat with peppermint water. To guard against relapse, the rheumatic patient should be clothed in flannel and lie between blankets. The modern use of the salicylates almost to the exclusion of the alkaline treatment he believed was responsible for a greater proportion of cardiac complications. He used aconite to quiet the heart, and cod-liver oil to improve the general condition, but considered iron mischievous in the anemia of rheumatism. He preferred the strontium salts to the salicylates.

DR. MORRIS MANGES was disposed to think that several germs might stand in etiological relation to rheumatism. He was of the opinion that more than 25 per cent. of cases were preceded by tonsillitis. The anemia was certainly very marked in rheumatism, but he had not found iron harmful. He was in the habit of using the organic preparations of iron. Many of the cardiac murmurs heard during an attack of rheumatism are hemic or myocardial, which explains the diurnal variations noted by Dr. Jackson. The best medicinal treatment for rheumatism was the use of the salicylates, together with the alkalies in sufficient quantity to keep the urine alkaline—often a difficult matter. Rest in bed during convalescence from rheumatism was of the utmost importance.

DR. S. BARUCH said that many of the disappointments with the salicylates arose from the use of too small doses. For some years past he had prescribed twenty-grain doses of pure salicylic acid from oil of wintergreen combined with ten-grain doses of bicarbonate of sodium, thus making the salicylate of soda extemporaneously. It was best to begin its administration at 4 p. m., and repeat at intervals of two hours until eighty grains have been taken. The drug should be given up to the point of producing a ringing in the ears, and if given only in the evening, the disagreeableness of the medicine would usually disappear during sleep. Locally, he made use of compresses of three or four thicknesses of linen wrung out of water at 60 F. and covered with flannel. They should be renewed about every two or three hours and were not usually required unless the temperature of the body was over 100 F.

DR. ABRAHAM MAYER said that while most physicians now believe in the bacterial nature of rheumatism, the specific germ was still unknown. He cited the experiments of Singer and Meyer in support of the view which he entertained, that rheumatism is caused by various germs. The impure varieties of salicylate often cause delirium, which is rarely true of the pure drug. With the latter he found it possible often to give 120 grains in the twenty-four hours without causing delirium. He had found iron useful.\*

DR. ANDREW H. SMITH said that he was accustomed to keep the urine of rheumatic patients alkaline by giving a mixture composed of equal parts of the acetate, bicarbonate and citrate of potassium. There was undoubtedly an intimate relation between tonsillar inflammation and acute articular rheumatism. A useful local application in acute articular rheumatism was made up of equal parts of guaiacol and glycerin. The patient should be confined to bed for some time after the temperature had reached the normal.

DR. LOUIS FISCHER, speaking of acute rheumatism in children, said that in his hospital cases of polyarthritis, 70 per cent. had developed heart complications and 11 per cent. of the cases had terminated fatally. The dietetic treatment was more important than the medicinal. The affected joints should be kept at rest by the use of bandages or splints. A 10 per cent. ointment of the salicylate of methyl applied to the affected joint would give relief in some cases. It was often useful to bathe the whole body of the child in water at 75 or 85 F., to which about two ounces of the sulphuret of potassium had been added.

DR. HEINRICH STERN said that the great number of bacteria found in connection with rheumatism tended to throw doubt upon the microbial theory. The salicylates act in rheumatism by increasing the osmotic tension of the blood.

DR. W. H. THOMSON said that he expected in the near future the announcement that Wassermann's bacterium had been demonstrated to be the ultimate cause of rheumatism.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### Treatment of Gallstone Colic.

G. S. Eveleth, in *New York Med. Jour.*, states that, in the treatment of gallstones, the first indication is the relief of pain by means of morphin administered hypodermically. One should bear in mind, however, the possibility of a rapid discharge of the stone and the immediate relief from pain. The second indication is the prevention of subsequent attacks by giving attention to the hygiene and diet; by the use of medicinal agents and by the aid of surgery.

In order to favor the respiratory and circulatory acts and thus increase metabolism, the following is recommended by him:

|                              |      |     |
|------------------------------|------|-----|
| R. Tinct. nucis vom. ....    | 3iii | 12  |
| Sodii salicylatis .....      | 5vi  | 24  |
| Ext. xanthoxyli flu. ....    | 3ii  | 60  |
| Elix. aurantii q. s. ad..... | 3vi  | 180 |

M. Sig.: One teaspoonful three times a day in water.

The nux vomica is given to increase the respirations and circulation, the sodium salicylate to increase the flow of bile, and the xanthoxylum for its tonic action upon the gastro-intestinal mucous membrane and to promote glandular action.

W. L. Heeve, in the same journal, states that biliary colic in mild form can always be relieved by the administration of 5-minim doses of a reliable fluid extract of *dioscorea villosa* every half hour in hot water. It may be given in the following combination:

|                                |         |     |
|--------------------------------|---------|-----|
| R. Ext. podophylli flu. ....   | m. xxiv | 150 |
| Ext. dioscoreæ vil. flu. ....  | 3iii    | 12  |
| Tinct. lobeliæ .....           | 3ii     | 8   |
| Aquæ chloroformi q. s. ad..... | 3iv     | 120 |

M. Sig.: One teaspoonful every half hour.

The action of olive oil, while not a specific, from his experience may be relied upon only when the obstruction is at the diverticulum of Vater, given in combination with aromatics in order that it may be better borne by the stomach:

|                          |        |     |
|--------------------------|--------|-----|
| R. Olei cinnamomi .....  | m. v   | 30  |
| Methyl salicylatis ..... | m. vi  | 35  |
| Menthol. ....            | gr. ss | 03  |
| Saccharini .....         | gr. i  | 06  |
| Essentiæ anisi .....     | m. xv  | 1   |
| Olei olivæ .....         | O. ss  | 240 |

M. Sig.: At one dose.

When the obstruction lies in the cystic ducts the internal administration of one-quarter grain doses of podophyllin until one grain has been given is recommended.

[*Dioscorea*—colic root—is an unofficial preparation made from the rhizome of the plant. It contains an acrid resin, which is perhaps the active ingredient acting upon and stimulating the intestinal canal. It has been used in the past in the form of the fluid extract to relieve the cramps in cholera morbus, spasmodic hicough, and biliary colic. But very few of the pharmacopeias speak of it at the present time.]

### Bromipin in Epilepsy.

Dr. J. Wolff, in *Allg. Med. Centralzeit.*, recommends bromipin in the treatment of epilepsy as a substitute for the bromids, because of the symptoms of intolerance and irritation of the stomach by the latter. According to his statement, bromipin did not so diminish the frequency of the attacks but was successful in lessening their severity. Also an improvement in the mental condition of the patients was very considerable. He gave to these patients bromipin in doses ranging from one and a half to six teaspoonfuls in the twenty-four hours. He observed no untoward effects from the drug. The functions of the body and the digestion were in no way disturbed by this treatment; on the other hand, the general nutrition of the patients were almost uniformly improved.

**Lupus Erythematosus.**

G. H. Fox, in the *Ther. Monthly*, recommends, where the patches are dry and scaly, an ointment or plaster of salicylic acid, gradually increased in strength until the inflammatory reaction is as great as the patient will tolerate. The following formula is recommended for local application:

|                           |        |     |
|---------------------------|--------|-----|
| R. Acidi salicylici ..... | gr. x  | 60  |
| Acidi pyrogallici .....   | gr. xx | 120 |
| Vaselini .....            | 3iii   | 12  |

M. Sig.: Apply locally once or twice daily.

**Epilepsy.**

In discussing the treatment of epilepsy, Bowman, as noted in the *Ther. Month.*, states that every effort should be made towards preventing the first paroxysm. Prophylaxis directed toward rachitis or defective nutrition may be exerted through proper feeding. Careful treatment through the acute infectious diseases, and the regulation of diet will prevent infantile convulsions. Hygienic measures can not be too strongly enforced. The patient, indeed, should live by the clock. Meat as a food should be forbidden absolutely or given in very small quantities. Keep watch on the enormous appetite of the epileptic. Forbid the use of alcohol and insist on the use of cold baths. Operations on the cortex may be considered in a certain proportion of cases of partial or traumatic epilepsy, but in no cases which have existed over two years. The bromids are relied upon for direct treatment. Strychnin is of value. Beta-naphthol is recommended by him as the best intestinal antiseptic. He states, however, that salol may be advantageously used and that it has a tendency to prevent the bad effects of the bromids.

**Scabies (Itch).**

The following is Kaposi's formula for the treatment of scabies:

|                        |       |    |
|------------------------|-------|----|
| R. Beta-naphthol ..... | 3iii  | 12 |
| Cretæ prep. ....       | 3iiss | 10 |
| Saponis mollis .....   | 3iii  | 12 |
| Adipis .....           | 3vi   | 90 |

M. Ft. unguentum. Sig.: Apply locally at night.

**Gonorrheal Urethritis.**

The following combinations are recommended in the treatment of gonorrheal urethritis:

|                     |        |    |
|---------------------|--------|----|
| R. Ichthargin ..... | gr. ss | 03 |
| Aquæ destil. ....   | 3iii   | 90 |

M. Sig.: Use in the form of an injection three times daily.

[Ichthargin is the sulpho-ichthyolate of silver. It is a brown odorless powder containing about 30 per cent. silver. It is soluble in water or glycerin, and is an astringent and bactericide.]

Internally the following is of service:

|                           |       |     |
|---------------------------|-------|-----|
| R. Copaibæ .....          | 3ii   | 8   |
| Salol .....               |       |     |
| Pulv. pepsini, āā .....   | 3iiss | 10  |
| Mucilag. acaciæ .....     | 3i    | 30  |
| Aquæ destil q. s. ad..... | 3iv   | 120 |

M. Sig.: Shake and take one teaspoonful three times a day.

**Cystitis.**

Dr. B. Foster, in *St. Paul Med. Jour.*, states that, in the treatment of cystitis, when the urine is acid in reaction, the following preparation containing liquor potassæ is the most useful:

|                                |     |     |
|--------------------------------|-----|-----|
| R. Liquoris potassæ .....      | 3ii | 8   |
| Mucilaginis acaciæ .....       | 3i  | 30  |
| Tinct. hyoseyami q. s. ad..... | 3iv | 120 |

M. Sig.: One teaspoonful every four hours in water.

If the urine is already alkaline, and particularly if it has undergone ammoniacal decomposition, urinary antiseptics are indicated, such as salol, boric acid, sodium benzoate or urotropin.

**Care of the Breasts in Nursing Mothers.**

Dr. G. Barksdale, in *West. Druggist*, recommends in the treatment of tender nipples, that the nipple be painted over with glycerite of tannin and alcohol for several days. If they

become fissured they should be painted with tincture of benzoin or boric acid solution. When the flow of milk is more than the child can use it is best to withdraw some of it to prevent pain to the mother. When the symptoms of abscess appear the child should be taken from the breast, the milk withdrawn and the tumors, produced by the overdistended ducts, should be masséed until they disappear; or the breast anointed with an ointment composed of camphor, opium, belladonna and lanolin. The pulverized jalup compound should also be given to secure free movement of the bowels and to promote diuresis. If the symptoms continue, use hot fomentations until the abscess forms and then open.

**Enuresis in Females.**

G. C. Parnell, as noted in the *Med. Standard*, in an extensive clinical practice has had occasion to treat many obstinate cases of enuresis in females of different ages. In an article in *Brit. Med. Jour.*, he reports five cases ranging in age from 9 to 18 years in which he applied a strong solution of silver nitrate to the neck of the bladder. Every case was benefited and one patient, 18 years of age, who had been a sufferer for ten years was permanently cured, and three of the others had only slight relapses. He used a wire dilator in applying the solution so as to reach the entire length of the urethra. No ointment or oil of any sort is used in its introduction. After the urine has ceased to flow a probe covered with cotton wool saturated with the solution is introduced between the blades of the dilator and applied thoroughly. The dilator is removed and again reinserted at right angles and the solution again applied to the surfaces. The strength of the solution should vary from gr. x (.60) to gr. l (.3) to the ounce (30) of water. Chloroform is not necessary, as the pain is not severe. The patient should be kept in bed for twenty-four hours and the application repeated in four or five days if necessary.

**Medicolegal.**

**Employment of Surgeon by Trainmaster.**—The Supreme Court of Mississippi says that the appealed case of the Southern Railway Company in Mississippi vs. Brister was brought to recover an agreed fee of \$100 for services to an employe of the company. It seems that the employe, while engaged in the company's service, was run over by one of its trains and seriously and, as it soon proved, fatally injured. The company's station agent at the place where the accident happened sent a call to the surgeon who rendered the services, whose services in like cases the company had before refused to compensate. The surgeon informed the station agent that he would attend the injured employe if he would be responsible for the fee. The agent asked him to wait a little, and, as the court infers, placed the case before the trainmaster, who wired the surgeon to take charge of the case for the fee of \$100, unless he was appointed the company's surgeon. The surgeon attended the wounded man, gave him all necessary medical attention and procured and paid for other necessary care and nursing, and after a few hours the patient died. The company not having engaged the doctor as one of its surgeons, he brought this action. The record disclosed the proof of the contract with the trainmaster for the payment of the \$100, the performance of the surgeon's part of the contract and the breach by the company. It was also proved by a former employe that the trainmaster had authority in emergencies to employ a surgeon temporarily and that the trainmaster also acted under the superintendent and performed the duties of local superintendent, which evidence was not objected to or controverted. Besides, so far as the record showed, the station agent was the only officer of the company on the spot, and it is assumed by the court that the trainmaster was the next officer of authority within reach. Under these circumstances, and with it admitted that this trainmaster might perhaps employ a surgeon in an emergency, the Supreme Court is of the opinion that he had authority to bind the company, and that the contract made was valid and enforceable. However, it says that it is not called upon to decide whether, as train-

master, he had authority to contract with the surgeon as he did; but, it says, inasmuch as at the time he was in the exercise of the functions of a division or local superintendent over that part of the road, it thinks it may be presumed that he had the power to so contract. From the fact that the company had surgeons in employ, though they were not in call, it infers that the company recognized its duty to employees injured in its service.

**Privilege in Nebraska—Board of Health Records.**—The Nebraska statute relating to witnesses and their competency contains the following provision relating to professional communications: "No practicing attorney, counsellor, physician, surgeon, minister of the gospel or priest of any denomination shall be allowed, in giving testimony, to disclose any confidential communication, properly entrusted to him in his professional capacity and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice or discipline."—Code of Civil Procedure, Section 333. "The prohibitions in the preceding sections do not apply to cases where the party in whose favor the respective provisions are enacted waives the right thereby conferred."—Section 334. The rule in Nebraska, as well as in other states having a like statute, the Supreme Court of Nebraska says, in *Sovereign Camp of Woodmen of the World vs. Grandon*, is that the above sections protect a party against any disclosure by a physician made to him in the course of his professional employment, and necessary and proper to enable him to discharge his duty to his patient. Not only are such communications privileged, but whatever knowledge the physician may gain from observing his condition and symptoms is likewise privileged. There can be no doubt as to the rights of the patient, and the courts, in a proper case, are vigilant to see that these rights are fully protected. But the fact that a physician was called to attend a patient is not a privileged communication. A physician may testify that he was called to attend a patient and to the number and dates of his professional visits. Moreover, where, in an action between the representative of a deceased person and an insurance company, the former introduced in evidence, as a part of the cross-examination of the attending physician, a written statement, which the latter had given her at her request, to the effect that the deceased was not seriously sick until the evening previous to his death, the court holds that this constituted a waiver of her privilege on her part, and that the company should have been permitted to re-examine the physician as to the condition of his patient. A record kept under the ordinances of a city for the evident purpose of assisting the board of health in the conduct of the affairs of that office, the court holds, is not such a public record as to be entitled to admission in evidence to show the truth of the matters therein recited and especially should it be rejected as evidence when offered to establish a fact which would not be admissible against a part because of its privileged character. That a record of this character, reciting privileged communications, may be used in evidence against a party where the testimony of the physician making it could not be received, the court says, is a proposition so inconsistent with reason and natural rules of justice that it can not give its consent thereto. Besides, the requirement, for example, of a city ordinance that, before a burial permit is issued, there must be filed with the secretary of the board of health a certificate setting forth the cause and date of death, the duration of the last illness of the deceased, etc., the court says is a mere police regulation, and is not intended for the purpose of supplying the public at large with information upon which reliance may be placed in the business affairs of the community.

**Damages for Injury to Physician's Business.**—The Supreme Judicial Court of Massachusetts says that the case of *Earle vs. Commonwealth* was brought by a practicing physician to recover for damage to his business by the carrying out of the Metropolitan Water Supply act. The case was referred to a commission. It reported that he lived and had his office in West Boylston and had a practice which extended through that and some neighboring towns. The taking of land at West Boylston necessarily affected his business to a considerable extent. The questions of law arising on the report were reserved

by one of the justices for the consideration of the full court. To begin with, the commonwealth contended that the material portion of the statute, if it applied to cases like this, in allowing damages, was unconstitutional. But the court pronounces it constitutional without stopping to consider whether the question was open, although it says that very likely the physician's rights were of a kind that might have been damaged if not destroyed without the constitutional necessity of compensation. Next it was contended that the physician was not an "individual \* \* \* owning \* \* \* an established business on land in the town of West Boylston" within the meaning of the statute. But a majority of the court does not see why not. It thinks the word "business" quite wide enough to include the practice of a doctor. As to the suggestion that the practice was not established on land in West Boylston, it says that it is true that a doctor can give advice elsewhere than in his office, and that in fact he does so to a greater extent than a shopkeeper sells his goods outside his shop. But no less than a shopkeeper a doctor usually has, as this one had, a locally established center to which patients resort, and from which he goes his rounds. There is even a certain amount of salable good will, as is made familiar to us by English law and literature as well as by an occasional case in our own reports. Then, the commonwealth demanded a finding or ruling that the physician's business was not decreased in value by the carrying out of the act, because of figures given for his income for the preceding year, and thereafter. But, the court says, the commission may have found, and for all that it can see, rightly, that the diminution of income before the date when the act should affect it was due to precautions taken by him in anticipation of the change and it is unable to see that the commonwealth's request should have been granted. If his business was within the protection of the act and was "decreased in value," damages were to be paid for "such injury," that is to say, for the actual decrease in value of that business, not for the decrease in the value of such elements in it, only, as admitted of being sold. The money value of his business could be estimated, even though absolutely personal to himself. Again, the court says that the damage theoretically would be the difference in value between the business as it had been and as it was left. Perhaps it might be reached by taking the difference in value between the business carried on as it was in West Boylston and a similar one carried on by the physician in the nearest available place, bearing in mind the effect of requiring all West Boylston patients to move. A request for a ruling that what the physician had earned as a specialist since his abandonment of his general practice could not be considered, the court says, went too far, though undoubtedly the evidence was not very important.

1.—See abstract in THE JOURNAL of April 12, p. 950.

2. The Kidney and Bladder in Infancy.—Morse has investigated the condition of the urine in every baby admitted to his service at the Infants' Hospital, Boston, for the last two years, as well as many in private practice. While his results are by no means complete, he thinks they are of importance.

The first urine of the newborn is acid, almost always clear, of rather low specific gravity and contains small quantities of albumin, often persisting for a couple of weeks and not infrequently for two months. He doubts whether any explanation offered for this has been correct. It is hardly sufficient to consider it physiologic, however, until more is known about the metabolic aspects in the newborn. In any case it is not a serious condition and should not be looked on as the forerunner of nephritis in later life. The evidences of uric acid infarction are present soon after birth and are found in more than 40 per cent. of the autopsies of the first week or two of life. In infancy the odor of the urine is slight, the color pale, and it is frequently turbid from mucus. The reaction is acid, with specific gravity as low as 1003 to 1008 for the first three months. The urine of breast-fed babies almost never contains indican and that of the artificially-fed baby only slight traces. Urobilin is never present in the breast-fed and seldom in the other. Albumin is absent and sugar is not found with the ordinary reagents. The sediment is slight and consists almost entirely of cells. The quantity of urine is usually large. Hematuria is found in infancy under the same conditions as in adult life. Acute nephritis may occur and the author feels certain that it is more frequent than generally supposed. It is difficult to say what influence it may have on the future of the child. The enormous reparative powers of the infants' tissues would make it probable that its power of harm is less than in adult life. A distinction must be made between the primary and secondary forms. His experience has been that while primary nephritis is seldom recognized, other conditions are not infrequently mistaken for it. Edema develops in many other diseases, but examination of the urine will prevent mistakes. As regards secondary nephritis, it complicates the eruptive fevers of infancy, as in childhood, but seems to develop more commonly in the pneumonias of infancy than in later life. He thinks it would be found more frequently in influenza if the urine were examined. The enteric diseases have been more studied than others, but he has found evidence of renal involvement in only 15 per cent. out of a series of 70 cases which he had investigated. Nephritis may occur also as a complication of eczema and suppurative ear disease, also from rickets, anemia, etc. Chronic nephritis is necessarily rare and where it occurs, heredity seems to be of etiologic importance. He has seen but a few cases. Acute pyelitis and pyelonephritis are not uncommon. A short time ago 2 of 18 babies in his service were found suffering from them. The secondary form is more common and the type usually mild. Primary cystitis is uncommon and usually not severe, but secondary cystitis is very common, and occurs in a great variety of cases. It is usually mild in type, but may be severe, and is rarely the result of upward extension of vulvovaginitis or urethritis. Both the primary and secondary forms are almost always due to the colon bacillus. The most usual source of invasion is probably the rectum. The symptoms of the primary forms are fever, restlessness and colicky pain and are easily misinterpreted. The diagnosis can be made only by examination of the urine. The symptoms of the secondary form are presumably the same. They are usually masked, however, by those of the primary disease. He says, in conclusion, that his experience leads him to believe that diseases of the kidneys and bladder are not at all uncommon in infancy and that the examination of the urine will render a diagnosis possible in many doubtful cases and throw light on many obscure symptoms. It is not enough to examine the urine only in cases in which diseases of the urinary organs are suggested, because the symptoms of these conditions in infancy are not only almost never characteristic, but usually misleading. It should be examined as a routine procedure, otherwise most of these cases will be missed, and diseases of these organs will continue to be as uncommon in the future as they have been in the past. If it is examined as a routine measure he feels sure there will be a very sudden increase in the frequency of these diseases, an increase, however, apparent rather than real.

4. Surgical Uses of the Hairpin.—Rugh describes the uses of the hairpin in surgery. It is serviceable to hold the hair

away from the shoulders and neck during an operation; to pin on bandages; to remove concretions or foreign bodies from any sinus, natural canal or opening. As a dull curette he thinks it of value and the points may be employed as an esthesiometer. It may be also utilized to catheterize the female by the insertion of the rounded end. If the points are bent slightly outward the danger of its slipping into the bladder will be obviated. It is also useful to run under a blood vessel with a figure-of-eight ligature, and the blunt ends make compression and prevent hemorrhage. It can also be employed to close wounds by running the arms through the tissues, on each side and then fastening the ends, thus keeping the skin edges compressed together in approximation. It can be employed also as a caliper or compass. Straightened out it can be used as an applicator; as a probe; to wire wounds together; to rupture the membranes in labor, and when heated, as a cautery; as harelip pins; to sound a child for stone in the bladder; as a hook to extract foreign bodies; and as a tenaculum. Bent or twisted, it can be used as a nasal speculum; as a retractor; as an aneurysmal needle; in lieu of the tracheotomy tube; as a drainage tube; and to approximate wounds. The illustrations give the different methods of its use.

**6. Appendicitis.**—From a number of cases here reported Patek calls attention to the forms of appendicitis having origin in an affection derived from some other part of the gastro-intestinal tract and urges vigorous action in such cases. He comes to the following conclusions: 1. Because of its anatomic characteristics and relations the appendix is an organ of lower vitality and less resistance than are other parts of the intestinal tract. 2. Micro-organisms are normally present in the intestine, and await but an opportune moment when, in the presence of irritating secretions, they may excite an inflammatory reaction. 3. While appendiceal inflammation may undoubtedly originate *de loco*, there is no question but that in many cases the appendiceal inflammation is a secondary infection, the primary focus being in the intestine proper, the result of an acute indigestion or a catarrhal inflammation. 4. While we can rarely make the positive assertion that a disease has through our efforts been aborted, he believes that prophylaxis is the price of health and that it may even be possible to do much toward the prevention of attacks of appendicitis, especially in the case of patients who have previously suffered, by careful attention to the regulation of diet and intestinal habit in health, no less than in securing good intestinal drainage and antisepsis in the various gastro-intestinal illnesses.

**7. Intermittent Claudication.**—Walton and Paul report a number of cases of this type and are inclined to believe arterial disease an important factor. They make suggestions also illustrated by cases, that some of the paroxysmal pains of degenerative spinal diseases—for example tabes—may be allied to this condition and have a peripheral rather than a spinal origin. Their conclusions are given as follows: 1. The concurrence of the paroxysmal pains of angina cruris with pulseless pedal arteries is too constant to be explained by coincidence, though it is true that pulseless arteries may be found without the pains, and, conversely, that such pains may appear with apparently normal arteries. 2. The painful paroxysms are probably of vascular origin, and result from vascular spasm coupled, perhaps, with increased blood pressure acting on vessels already partially occluded, whether from local or general disease (aneurysm, syphilis), from senile changes (atheroma), or from congenital tendency to angiofibrosis. 3. Recurring painful cramps of constant seat probably represent a modified form of angina cruris. 4. It is important to examine the dorsalis pedis and posterior tibial, as well as the radial and temporal arteries, in all cases in which it is desirable to estimate the bearing of the vascular condition upon disease in the central nervous system or elsewhere.

**8. Physiologic Heart Murmurs.**—Howell has experimented with a number of patients to determine the cause of murmurs produced in them after the use of the electric-light bath. Of the 22 carefully collected cases of males only one had an organic murmur, and only one a functional murmur prior

to the bath. This was in a nervous but otherwise healthy man. Out of the 22 there was only one in whom the murmur was not produced by the bath. Of the 29 females a larger proportion had organic and functional murmurs, 12 in all. In only one of all these did he fail to hear a murmur after the bath; in this case the bath was short, and this was probably responsible for the failure. He speaks of the causes of functional non-organic murmur, and has come to believe that anything that causes the heart to act rapidly and forcibly, especially where arterial tension is reduced, will frequently produce these murmurs, therefore heart disease may be wrongly diagnosed when conditions are present which may thus excite the murmurs. He says in conclusion, "given a condition of temporarily dilated aorta and a vigorously acting heart rapidly forcing the blood through a relatively narrow aortic orifice, it seems reasonable to suppose that vortices should form as the blood enters the artery, and that they in turn should produce the sounds we term murmurs."

**14. Sewage Purification.**—Buxton describes the methods of sewage purification, more particularly the septic tank system. The different processes are tabulated and the septic tank method recommended as best meeting the difficulties, especially the Cameron system, which seems to be largely employed throughout Great Britain, the Scott-Monerieff plan being only exceptionally in use.
